Hepatic steatosis is caused by metabolic imbalances that could be explained in part by an increase in de novo lipogenesis that results from increased sterol element binding protein 1 (SREBP-1) activity. The nuclear receptor liver receptor homolog 1 (LRH-1) is an important regulator of intermediary metabolism in the liver, but its role in regulating lipogenesis is not well understood. Here, we have assessed the contribution of LRH-1 SUMOylation to the development of nonalcoholic fatty liver disease (NAFLD). Mice expressing a SUMOylation-defective mutant of LRH-1 (LRH-1 K289R mice) developed NAFLD and early signs of nonalcoholic steatohepatitis (NASH) when challenged with a lipogenic, high-fat, high-sucrose diet. Moreover, we observed that the LRH-1 K289R mutation induced the expression of oxysterol binding protein-like 3 (OSBPL3), enhanced SREBP-1 processing, and promoted de novo lipogenesis. Mechanistically, we demonstrated that ectopic expression of OSBPL3 facilitates SREBP-1 processing in WT mice, while silencing hepatic Osbpl3 reverses the lipogenic phenotype of LRH-1 K289R mice. These findings suggest that compromised SUMOylation of LRH-1 promotes the development of NAFLD under lipogenic conditions through regulation of OSBPL3.

Introduction

Hepatic steatosis is characterized by the excessive accumulation of triglycerides as a consequence of an imbalance between the acquisition and disposal of fatty acids. Increased hepatic uptake of adipose tissue–derived fatty acids, defective breakdown via β-oxidation, reduced VLDL-triglyceride secretion, and induced activity of master regulators of de novo lipogenesis, such as sterol element binding protein 1 (SREBP-1, encoded by Srebf1), are factors that contribute to the development of steatosis (1). Nonalcoholic fatty liver disease (NAFLD) comprises a spectrum of disorders, of which the earliest stage is characterized by the deposition of lipid droplets within the cytoplasm of the hepatocytes. NAFLD increases the susceptibility to hepatocyte damage and inflammation, a condition termed nonalcoholic steatohepatitis (NASH), and can ultimately progress to cirrhosis and hepatocellular carcinoma (HCC) (1–4).

Liver receptor homolog 1 (LRH-1) is a nuclear receptor with diverse biological functions ranging from cell cycle regulation to the control of steroid homeostasis. In the liver, LRH-1 is an important regulator of glucose, cholesterol, and bile acid metabolism (5). Liver-specific Lrh-1 knockout mice display reduced glycolytic flux and de novo lipogenesis secondary to impaired glucokinase activity (6). On the other hand, treatment of mice with the LRH-1 agonist 1,2-dilauroyl-sn-glycero-3-phosphocholine (DLPC) protects animals from developing NAFLD and insulin resistance in genetic and dietary models of diabesity (7, 8). To address this apparent contradictory role of LRH-1 in hepatic triglyceride metabolism, we chose to study lipogenesis in our recently described Lrh-1 K289R knockin mouse model (LRH-1 K289R mice), which displays selective gain of function of LRH-1 as a result of impaired SUMOylation at K289 (9).

In this study, we demonstrate that LRH-1 K289R induces the expression of oxysterol binding protein-like 3 (OSBPL3, encoded by Osbpl3, also known as Orp3), which in turn promotes the posttranslational activation of SREBP-1. As a consequence, LRH-1 K289R mice display increased de novo lipogenesis upon refeeding in comparison with WT mice. In fact, compared with what is seen in LRH-1 WT mice, this chronic lipogenic stress promotes NAFLD in LRH-1 K289R mice accompanied by early signs of NASH when mice are exposed to a lipogenic, high-fat, high-sucrose (HFHS) diet.

Results

Increased hepatic SREBP-1 processing in LRH-1 K289R mice. In order to evaluate the role of an LRH-1 SUMO–defective pathway on intermediary liver metabolism, we subjected LRH-1 K289R mice, which exhibit partial gain of function of LRH-1, and control LRH-1 WT mice (9) to fasting-refeeding challenges in which mice were fasted and then refed for a period of 6 hours. We then evaluated the expression of metabolic genes in refeed livers of both genotypes using microarray analysis. Interestingly, the expression of
Figure 1. LRH-1 K289R mice display increased de novo lipogenesis. (A) Heat map showing the expression of genes involved in de novo fatty acid and cholesterol synthesis in refed WT and K289R mice. Normalized expression values are in log2 scale. For all other transcripts P < 0.05. (B) Hepatic mRNA expression of Srebf1 in K289R and WT mice. n = 10 per genotype. (C) Left, immunoblots of precursor and cleaved (cl) SREBP-1, SCD1, HSP90, and P62 in hepatic lysates of WT or K289R livers. Right, graph displaying the ratio of cleaved to precursor SREBP-1. (D) Representative images of liver sections of K289R or WT mice stained with oil red O to visualize neutral lipids. Scale bar: 200 μm. (E) Quantification of hepatic triglyceride content in WT and K289R mice. n = 10 per group. (F and G) Plasma triglyceride (TG) and free fatty acid (FFA) contents in WT and K289R mice. n = 10 per group. (H–J) Fractional de novo synthesis rates of palmitate (H), stearate (I), and oleate (J) in WT and K289R mice. n = 6 per group. Error bars represent mean ± SEM. *P < 0.05, **P < 0.01 relative to WT within each nutritional state; *P < 0.001 refed relative to fasted mice, as determined by unpaired Student’s t test (A) or 2-way ANOVA with Bonferroni’s post-hoc test (B, C, E–J). WT, LRH-1 WT; K289R, LRH-1 K289R mice.

many SREBP-1 target genes was increased in 6-hour–refed LRH-1 K289R compared with LRH-1 WT livers, whereas SREBP-2 targets were not altered (Figure 1A). Although no changes in Srebf1 mRNA (Figure 1B) or uncleaved precursor SREBP-1 (Figure 1C) could be observed between both genotypes, refed LRH-1 K289R livers displayed significantly more of the cleaved and transcriptionally active SREBP-1 protein in comparison with the LRH-1 WT livers (Figure 1C), indicating that the posttranslational processing and maturation of SREBP-1 is increased in LRH-1 K289R mice. We then performed acute insulin challenges as well as shorter 2-hour refeeding experiments to analyze whether early signaling events could explain the increased SREBP-1 activity. Insulin did not induce an additional increase in AKT phosphorylation or a consistent induction of early response genes, such as activating transcription factor 3 (Atf3) or early growth response 1 (Egr1) (Supplementary Figure 1, A and B; supplemental material available online with this article; https://doi.org/10.1172/JCI85499DS1) (10, 11), in LRH-1 K289R versus LRH-1 WT livers. Similarly, we did not observe differences in Srebfla and Srebfic expression in 2-, 6-, or 12-hour–refed LRH-1 K289R and LRH-1 WT mice (Supplemental Figure 1C). Taken together, these data suggest that LRH-1 K289R induces SREBP-1 signaling primarily at the posttranscriptional level independently of early insulin-AKT signaling.

Enhanced de novo lipogenesis in LRH-1 K289R mice. To verify whether the increased expression of lipogenic genes is accompanied by hepatic fat accumulation, we next quantified hepatic triglyceride content in LRH-1 K289R and LRH-1 WT mice. The content of neutral lipids and triglycerides was significantly increased in LRH-1 K289R compared with LRH-1 WT livers upon refeeding (Figure 1, D and E). Of note, plasma triglycerides and free fatty
acids did not show significant alterations between LRH-1 K289R and LRH-1 WT mice (Figure 1, F and G). To verify whether the enhanced expression of lipogenic genes translates into increased de novo lipogenesis, animals received 13C-acetate prior to sacrifice to quantify de novo lipogenesis (6). In line with the increased lipogenic gene expression, de novo synthesis of palmitate (C16:0), stearate (C18:0), and oleate (C18:1) was significantly higher in LRH-1 K289R compared with LRH-1 WT livers (Figure 1, H–J). Of note, chain elongation of preexisting fatty acids was not altered between the 2 genotypes (Supplemental Figure 1, D and E). Collectively, these data show that LRH-1 K289R mice display increased de novo lipogenesis and that enhanced activation of SREBP-1 likely contributes to this process.

**SUMOylation-defective LRH-1 drives the expression of Osbpl3.** We next analyzed the transcriptome of livers from refed LRH-1 K289R and LRH-1 WT mice and searched for transcripts that are linked to SREBP-1 processing. One of the top hits on the list of genes that was increased in LRH-1 K289R compared with LRH-1 WT livers corresponded to Osbpl3, a member of a class of lipid transfer proteins recently implicated in the shuttling of lipids between the plasma and endoplasmic reticulum membrane (12–14). The expression of Osbpl3, and to a lesser extent Osbpl1a, was robustly induced in LRH-1 K289R livers, while that of most other OSBP family members did not differ between the 2 genotypes (Figure 2A). Of interest, overexpression of certain oxysterol-binding proteins has been suggested as increasing SREBP-1 processing and hepatic lipogenesis (15). Analysis of livers of LRH-1 K289R versus LRH-1 WT mice confirmed the enhanced expression of Osbpl3 mRNA during fasting and refeeding (Figure 2B), while the expression of other OSBP family members did not differ between the 2 genotypes (Supplemental Figure 2A). Notably, the expression of Osbpl3 was high during fasting and then reduced upon refeeding (Figure 2B). This postprandial suppression of Osbpl3 mRNA expression was also observed upon overexpression of Osbpl3 in mice using an adenovirus (Supplemental Figure 2B), suggesting that during the refed state, Osbpl3 is regulated by posttranscriptional mechanisms occurring independently of LRH-1. Despite this feeding-dependent regulation of the mRNA, hepatic Osbpl3 mRNA levels were consistently higher in the LRH-1 K289R
LRH-1 target genes, including lipogenic genes, are coregulated by members of the LXR subfamily (20–22), we assessed the possibility that the LRH-1 mutant may modulate the recruitment of LXR to its target genes, Abca1, Chrebp, and Srebf1. Although recruitment of LXRα was detected on these promoters in the genomic lysates of LRH-1 K289R and LRH-1 WT livers, no differences were observed between both genotypes, suggesting that LXRα binding is not altered due to the LRH-1 K289R mutation (Supplemental Figure 3A). Furthermore, Hepa 1.6 and AML-12 cells treated with the LXR agonist GW3965 did not alter Osbpl3 expression (Supplemental Figure 3, B and C), indicating that Osbpl3 expression is not regulated by LXR.

Osbpl3 silencing rescues the steatotic phenotype of LRH-1 K289R mice. To establish whether the increased expression of OSBPL3 in LRH-1 K289R livers is causatively linked to exacerbated de novo lipogenesis, we performed in vivo overexpression and silencing experiments. Adenoviral overexpression of OSBPL3 increased mice in all nutritional states, but were particularly high under 6-hour–refeeding conditions (Figure 2C), and these differences were translated into similar changes at the protein level (Figure 2D).

To investigate whether Osbpl3 is directly controlled by LRH-1, we first analyzed the Osbpl3 genomic region in available ChIP-Seq data for potential LRH-1–binding sites (16, 17). We identified 3 main sites from the ChIP-Seq data from Holmstrom et al. (sites 1–3; ref. 16), and 3 additional sites with an LRH-1 consensus sequence close to one of the transcription start sites of the Osbpl3 gene (sites 4–6) were identified by computational analysis (Figure 2E). We then performed site-specific ChIP analysis to evaluate whether these sites are bound by LRH-1 in fasted and refed mice. LRH-1 was recruited at different sites under both nutritional conditions (Figure 2, F and G), suggesting that Osbpl3 is a direct LRH-1 target gene.

Based on the fact that LRH-1 and the nuclear receptor liver X receptor (LXR) have been shown to crosstalk in the regulation of hepatic acute-phase response proteins (18, 19) and that various LRH-1 target genes, including lipogenic genes, are coregulated by members of the LXR subfamily (20–22), we assessed the possibility that the LRH-1 mutant may modulate the recruitment of LXRα to its target genes, Abca1, Chrebp, and Srebf1. Although recruitment of LXRα was detected on these promoters in the genomic lysates of LRH-1 K289R and LRH-1 WT livers, no differences were observed between both genotypes, suggesting that LXRα binding is not altered due to the LRH-1 K289R mutation (Supplemental Figure 3A). Furthermore, Hepa 1.6 and AML-12 cells treated with the LXR agonist GW3965 did not alter Osbpl3 expression (Supplemental Figure 3, B and C), indicating that Osbpl3 expression is not regulated by LXR.

Osbpl3 silencing rescues the steatotic phenotype of LRH-1 K289R mice. To establish whether the increased expression of OSBPL3 in LRH-1 K289R livers is causatively linked to exacerbated de novo lipogenesis, we performed in vivo overexpression and silencing experiments. Adenoviral overexpression of OSBPL3 increased...
expression levels of the lipogenic enzymes acetyl–coenzyme A carboxylase alpha (Acaca), Fasn, Scd1, and glycerol-3-phosphate acyltransferase (Gpam) were often normalized to values observed in LRH-1 WT mice (Figure 3G), suggesting that Osbpl3 silencing rescues the lipogenic phenotype of LRH-1 K289R mice. In line with the reduced expression of lipogenic genes, Osbpl3 silencing also decreased hepatic triglyceride and neutral lipid content (Figure 3H). As an additional approach to silence Osbpl3, we injected mice with an AAV8 viral vector containing an miRNA targeting Osbpl3 in the liver. Here again, we observed a robust silencing of Osbpl3, which was accompanied by the suppression of Fasn and a striking reduction of hepatic lipid droplets (Figure 3, I–K).

Finally, we also examined whether other mechanisms, directly or indirectly regulated by LRH-1, may contribute to the lipogenic phenotype. Of interest, both hepatic glucose-6-phosphate content (6) and VLDL secretion (23) were unchanged between SREBP-1 cleavage in refeed LRH-1 WT mice (Figure 3A), suggesting that elevated OSBPL3 levels promote SREBP-1 activation. We next silenced Osbpl3 in LRH-1 K289R mice using siRNAs in LRH-1 K289R mice under fast-refeeding conditions. The hepatic mRNA expression of Osbpl3 showed a clear trend of effective silencing (Figure 3B), while Srebf1 expression was not altered (Figure 3C). Importantly, we observed a robust decrease in OSBPL3 protein along with a reduction in the maturation of SREBP-1 and a blunted expression of the fatty acid synthase (FASN) transcript and protein in the livers of refeed LRH-1 K289R mice treated with siOsbpl3 (Figure 3, D and E). We next assessed the effect of Osbpl3 silencing under normal-fed conditions. Western blot analysis revealed reduced OSBPL3 expression (Figure 3F) and a robust decrease in the lipogenic proteins FASN and stearoyl–coenzyme A desaturase 1 (SCD-1) in ad libitum–fed LRH-1 K289R mice treated with siOsbpl3 compared with control mice (Figure 3F). Of interest, mRNA expression levels of the lipogenic enzymes acetyl–coenzyme A carboxylase alpha (Acaca), Fasn, Scd1, and glycerol-3-phosphate acyltransferase (Gpam) were often normalized to values observed in LRH-1 WT mice (Figure 3G), suggesting that Osbpl3 silencing rescues the lipogenic phenotype of LRH-1 K289R mice. In line with the reduced expression of lipogenic genes, Osbpl3 silencing also decreased hepatic triglyceride and neutral lipid content (Figure 3H). As an additional approach to silence Osbpl3, we injected mice with an AAV8 viral vector containing an miRNA targeting Osbpl3 in the liver. Here again, we observed a robust silencing of Osbpl3, which was accompanied by the suppression of Fasn and a striking reduction of hepatic lipid droplets (Figure 3, I–K).
LRH-1 K289R and LRH-1 WT mice (Supplemental Figure 4, A–C), making it unlikely that these processes account for the exacerbated lipid accumulation in liver.

Together, these data suggest that the LRH-1-OSBPL3 signaling axis contributes to the increased maturation of SREBP-1, the induction of lipogenic enzymes, and the hepatic accumulation of triglycerides observed in LRH-1 K289R mice.

LRH-1 K289R mice are prone to developing NAFLD upon lipogenic diet feeding. Excessive de novo lipogenesis contributes to the development of NAFLD, a condition that can eventually progress to NASH (1, 3). In order to investigate whether LRH-1 affects the development of NAFLD, LRH-1 K289R and LRH-1 WT mice were fed a highly lipogenic HFHS diet or a chow diet for 17 weeks, and then sacrificed under normal-fed conditions. Stainings of hepatic sections with H&E and oil red O revealed that LRH-1 K289R mice developed a stronger steatotic phenotype compared with LRH-1 WT mice (Figure 4A). While plasma cholesterol levels were unchanged (Supplemental Figure 5A), triglyceride content in plasma (Figure 4B) or in VLDL fractions (Supplemental Figure 5B) was reduced in HFHS-fed LRH-1 K289R mice. This reduction was accompanied with a robust accumulation of hepatic triglycerides (Figure 4C) as well as an induction of plasma levels of the enzymes alanine transaminase (ALAT) and aspartate aminotransferase (ASAT) in the HFHS-challenged LRH-1 K289R mice (Figure 4, D and E). Similar to our earlier observations in normal chow diet conditions (Figure 2, A–D), Osbp3 mRNA and OSBPL3 protein were significantly induced in LRH-1 K289R compared with LRH-1 WT mice fed a HFHS diet (Figure 4, F and G), while the expression of other Osbp genes did not differ between the genotypes (Supplemental Figure 5C).

The development of hepatic steatosis in mice is known to be highly heterogeneous (24). Therefore, we analyzed the data from a study in which mice were fed a chow or high-fat diet and then classified according to the development of NAFLD/NASH into low-fat low (LFL) responders, low-fat high (LFH) responders, high-fat low (HFL) responders, and high-fat high (HFH) responders (24). Interestingly, the expression of Osbp3 was significantly induced in the HFH responders along with markers of inflammation and

Figure 5. LRH-1 K289R mice display increased inflammation and early signs of fibrosis upon HFHS diet feeding. (A) Representative images of liver sections of K289R or WT mice stained with sirius red or CD45 to visualize collagen depositions and CD45-positive cells, respectively. Scale bars: 200 μm. CV, central vein. (B–E) Hepatic mRNA expression of genes involved in inflammation (B), matrix degradation (C), fibrosis (D), and stellate cells (E) in K289R and WT mice. n = 9 per genotype. (F) Graphical presentation showing how the LRH-1/OSBPL3 axis drives the accumulation of hepatic lipids. Error bars represent mean ± SEM. *P < 0.05, **P < 0.01, ***P < 0.001 relative to WT within each diet, as determined by 2-way ANOVA with Bonferroni’s post-hoc test (B–E).
necrosis (Figure 4H) and was by far the most strikingly increased Osbp among all family members (Supplemental Figure 5D). We also analyzed OSBPL3 expression in 2 cohorts of NAFLD/NASH patients. In the first cohort, livers were categorized as showing mild or advanced NAFLD (25). In the second study, subjects had livers ranging from healthy controls to showing steatosis and further to NASH (26). OSBPL3 expression was low in healthy livers, but increased in advanced stages of NAFLD/NASH and clustered with markers of fibrosis (Figure 4I and Supplemental Figure 6), suggesting that OSBPL3 could be a novel biomarker for advanced liver diseases, such as NASH. Taken together, these data show that Osbpl3 is markedly increased in LRH-1 K289R mice as well as in mice and humans with NAFLD/NASH.

LRH-1 K289R mice display increased inflammation and early signs of fibrosis in response to lipogenic diet feeding. Given the strong steatotic phenotype and the high levels of ALAT and ASAT markers in LRH-1 K289R mice fed a HFHS diet as well as the clustering of Osbpl3 with genes involved in inflammation and fibrosis in mice and humans with NAFLD, we next analyzed inflammatory and fibrotic markers in LRH-1 K289R and LRH-1 WT mice. Stainings of hepatic sections with sirius red and CD45 revealed that, in contrast with LRH-1 WT mice, LRH-1 K289R mice developed small fibrotic lesions and accumulated CD45-positive immune cells upon HFHS feeding (Figure 5A). Moreover, LRH-1 K289R livers displayed higher levels of the inflammatory genes Tnfα, monocyte chemoattractant protein-1 (Mcp1 or Ccl2), and macrophage inflammatory protein-1 α (Mip1α or Ccl3) (Figure 5B), indicating increased inflammation in livers of HFHS-fed LRH-1 K289R mice. The expression of MMPs, such as Mmp2 and Mmp13, as well as early markers of fibrosis, such as α-1 type I collagen (Col1a1) and Tgfβ1, was also elevated in LRH-1 K289R in comparison with LRH-1 WT mice fed a HFHS diet (Figure 5, C and D). Hepatic stellate cells are the primary hepatic cell type promoting fibrogenesis (27). The expression of different hepatic stellate cell markers, such as desmin (Des), glial fibrillary acidic protein (Gfap), and reelin (Reln), was also increased in HFHS-fed LRH-1 K289R compared with LRH-1 WT mice (Figure 5E), suggesting that HFHS-treated LRH-1 K289R mice exhibit early signs of NASH.

Previous studies showed that LRH-1 and the SUMOylation machinery might affect the hepatic acute phase response (APR) (18, 19, 28). While induction of the APR by short exposure of LPS led to reduced hepatic expression of Crp and Tnf in LRH-1 K289R compared with LRH-1 WT mice, it did not alter the hepatic expression of other APR and inflammatory genes (Supplemental Figure 7A). Moreover, no difference in plasma IL-6, MCP-1 (also known as CCl-2), or Tnf-α could be observed in LPS-challenged LRH-1 K289R and LRH-1 WT mice (Supplemental Figure 7B), suggesting that the APR is likely not driving the observed inflammatory phenotype in our NAFLD-model.

Taken together, these data show that SUMOylation-defective LRH-1 promotes the development of NAFLD and displays early signs of NASH in mice fed a HFHS diet. This process is at least partially driven by the LRH-1-OSBPL3 signaling axis, which contributes to increased maturation of SREBP-1, the induction of lipogenic enzyme expression, and hepatic triglyceride accumulation in LRH-1 K289R mice (Figure 5F).

Discussion

In this study, we analyzed the contribution of a selective LRH-1 gain of function on hepatic de novo lipogenesis and fatty liver development and identified Osbpl3 as a critical component in the regulation of this process. While the hepatic expression of Osbpl3 is normally low in mice under basal conditions, LRH-1 K289R mice express high levels of this specific OSBP family member. Consistent with our observations, the analyses of independent mouse and human transcriptomic data sets revealed that Osbpl3 expression is often induced in NAFLD/NASH. Our work furthermore strengthens the putative role of OSBPL3 in SREBP-1 maturation. As a consequence, LRH-1 K289R mice display increased de novo lipogenesis and accumulation of triglycerides upon refeeding in a manner that is independent of enhanced LXRs recruitment or activity. Importantly, silencing of OSBPL3 in vivo reverts the increased lipogenesis observed in these animals. Moreover, when exposed to a lipogenic HFHS diet, LRH-1 K289R mice develop NAFLD accompanied by early signs of NASH, most likely as a consequence of chronic fat accumulation (1, 3).

The excessive accumulation of hepatic lipids and increased de novo lipogenesis could also have other causes. A previous study using liver-specific Lrh-1 knockout mice showed that LRH-1 promotes glucokinase expression, hence regulating glycolysis and de novo lipogenesis (6). However, we did not observe a difference in hepatic glucose-6-phosphate content between LRH-1 WT and LRH-1 K289R mice, suggesting that the selective gain of function of LRH-1 driven by the K289R mutation does not increase substrate availability for the glycolytic pathway. Based on the finding that the primary corepressor of LRH-1 affects microsomal triglyceride transfer protein levels and consequently hepatic VLDL-triglyceride secretion (23), we also performed in vivo VLDL-secretion assays, but could not detect any difference between refed LRH-1 K289R and LRH-1 WT mice. Finally, LRH-1 SUMOylation has been linked to the induction of the hepatic APR (18, 19, 28), which could explain the excessive inflammation observed in the livers of mice receiving a chronic HFHS diet. To study the APR in vivo, we challenged LRH-1 WT and LRH-1 K289R mice with lipopolysaccharide for 2.5 hours. Besides the reduction in Crp and Tnf, the inflammatory signature was comparable between the genotypes, suggesting that the exacerbated inflammatory phenotype of the LRH-1 K289R mice is most likely not driven by changes in the APR.

While the induction of SREBP-2 processing has been well described, the mechanisms that trigger SREBP-1 processing are less well understood (29). Insulin receptor/AKT/mTOR signaling is considered one of the main pathways triggering SREBP-1 signaling (30). A recent study showed that insulin promotes SREBP-1 activation and de novo lipogenesis via mTORC1-dependent and -independent mechanisms (31). Others proposed that while insulin signaling is required for SREBP-1 activation in insulin-resistant conditions, it is not critical for inducing the feeding-dependent induction of SREBP-1 under physiological conditions (32, 33). In breast epithelial cells, the expression of oncogenic forms of the PI3K or K-Ras are sufficient to induce SREBP-1 maturation and de novo lipogenesis through induction of mTOR signaling (34). Whereas these and many other studies demonstrate that the expression of Sreb1a and the posttranslational maturation of SREBP-1 can be triggered by insulin signaling, other downstream factors might contribute to the regulation of SREBP-1 processing.
or parallel pathways exist. One recent example is the induction of SREBP-1 processing upon depletion of phosphatidylcholine, whose synthesis is dependent on S-adenosylmethionine, a methionine derivative that is generated in the one-carbon cycle (35). We did not observe a difference in AKT phosphorylation between LRH-1 WT and LRH-1 K289R mice, suggesting other signaling pathways to induce the processing of SREBP-1. Indeed, our current study highlights the existence of an alternative mechanism of SREBP-1 activation involving a SUMO-dependent LRH-1/OSBPL3 pathway.

The first oxysterol-binding proteins were identified, purified, and cloned in the 1980s (36–38). Recent studies suggest that OSBPs act as sterol transfer and/or sensor proteins that may also play important roles in cell signaling (39, 40). OSBPL3, a member of subfamily III, contains a conserved sterol-binding OSBP homology domain (OHD) as well as a phosphatidylinositol lipid species–binding pleckstrin homology (PH) domain and two 2-phenylalanines in an acidic tract (FFAT) domains that bind to the vesicle-associated membrane protein–associated (VAMP-associated) protein (VAP) (39, 41, 42). Recently, it has been shown that this last interaction can activate R-RAS, thus reorganizing the actin cytoskeleton and affecting cell polarity and cell-cell adhesion (43). Future studies will be necessary to dissect the exact mechanisms by which OSBPL3 modulates SREBP-1 processing, but its association with the ER could indicate a possible site of regulation.

In addition to the identification of OSBPL3 as a target of LRH-1, our study also highlights the existence of complex regulatory mechanisms to which OSBPL3 is subjected. We observed a discrepancy between mRNA and protein levels of OSBPL3 between fasting and refeed conditions despite its persistent increase in LRH-1 K289R mice. The marked reduction in mRNA levels upon refeeding was also noticed when OSBPL3 was overexpressed using an adenovirus, indicating that additional posttranscriptional mechanisms independent of LRH-1 regulate the expression of OSBPL3. Moreover, while the expression of OSBPL3 is low in healthy livers, it is increased in NAFLD, suggesting that this protein could be a novel biomarker for NAFLD.

In this study, we described a function of LRH-1 in the development of fatty liver disease. It is noteworthy that other nuclear receptors also contribute to the development of NAFLD by affecting steatosis, glucose homeostasis, inflammation, and/or fibrosis in the liver. For instance, while activation of LXRs or pregnancy x receptor (PXR) promotes lipogenesis and the development of NAFLD, activation of other nuclear receptors such as PPARs or farnesoid X-activated receptor (FXR) has opposite effects (reviewed in ref. 44). Clinical trials performed in NASH patients using PPARy or FXR agonists showed that the beneficial effects observed on hepatic steatosis and inflammation were accompanied by adverse effects on obesity and hypercholesterolemia, respectively (45, 46), highlighting the functional complexity of nuclear receptors (44). Therefore, the development of drugs targeting specific nuclear receptor targets, such as OSBPL3, might provide alternative therapeutic options for treating NAFLD.

**Methods**

**Animal studies.** Congenic C57BL/6J LRH-1 WT or LRH-1 K289R (9) as well as C57BL/6J Lrh-1–/– and Lrh-1–/– mice (6) were kept under normal housing conditions. For fast-reefeding protocols, 12- to 16-week-old male mice were initially fasted for 24 hours, followed by refeeding for 12 hours (8 pm to 8 am), 6 hours (2 am to 8 am), or 2 hours (6 am to 8 am), and finally sacrificed together at 8 am to avoid confounding effects of the circadian rhythm. To induce a chronic hepatic steatosis, male mice were fed ad libitum with a HFHS diet (TD.08811, Harlan Laboratories) for 17 weeks and sacrificed at 9 am. To study the APR, male mice fed a chow diet received an intraperitoneal injection of either 500 μl PBS or 40 μg LPS dissolved in 500 μl PBS. Mice were sacrificed 2.5 hours after injection and tissues collected.

**Subcellular fractionation of liver tissues and Western blotting.** From 50 to 100 mg of liver pieces were incubated in 400 μl of hypotonic buffer (10 mM HEPES-KOH, pH 7.4, 10 mM KCl, 1.5 mM MgCl₂, 0.5 mM DTT, protease and phosphatase inhibitor cocktails; Roche) and lysed with 10 strokes in a Dounce homogenizer. The supernatant fraction containing mainly cytoplasmic proteins was collected after centrifugation (14,000 g for 5 minutes, 4°C), and the pellets were washed twice with hypotonic buffer. The pellets were resuspended in 100 to 200 μl of hypertonic buffer (50 mM Tris-HCl pH 7.4, 150 mM NaCl, 0.1% NP-40, protease and phosphatase inhibitor cocktails) for 30 minutes on ice. The supernatant containing mainly nucleoplasm and membrane fractions was collected by centrifugation (2,000 g for 5 minutes, 4°C), and the remaining insoluble pellet containing mainly chromatin was resuspended in 100 μl of hypertonic buffer and sonicated. Before running SDS-PAGE, protein lysates were boiled for 5 minutes at 95°C. The following proteins were used for Western blotting: anti-Hsp90, anti–SREBP-1, and anti-P62 (BD Biosciences catalog 610418, 557036, and 610497); anti–OSBPL3 (Novus Biologicals, catalog NBP-155151), anti-FASN (Abcam, catalog ab22759), anti-SCD1 (Thermo Fisher, catalog A13996), anti-α-tubulin, anti-PARP1, and anti-β-actin (Santa Cruz Biotechnology Inc., catalog sc-5286, sc-7150, and sc-47778). Anti–SREBP-1, anti-P62, and anti-PARP1 were blotted on nuclear/membrane fractions and all other antibodies on cytoplasmic fractions.

Gene expression and analysis. RNA was extracted from the livers of mice that were fasted for 24 hours followed by 6 hours of refeeding, LRH-1 WT (n = 6) and LRH-1 K289R (n = 6). Extraction was performed using TRIZOL (Invitrogen) and purified with the RNeasy Cleanup Kit for Microarray Analysis (QIAGEN). For quantitative reverse-transcription PCR (RT-qPCR), cDNA was generated using the Quantitect Reverse Transcription Kit (QIAGEN) and analyzed by qPCR using a LightCycler 480 Real-Time PCR System (Roche) and the primers listed in Supplemental Table 1. Expression data were normalized to 36b4 or B2m mRNA levels. Microarray analysis was performed using the Affymetrix MouseGene 1.0 ST array and normalized using the robust multi-array average (RMA) method. All original microarray data were deposited in the NCBI’s Gene Expression Omnibus (GEO GSE89877). Heat maps were generated using GENE-E (http://www.broadinstitute.org/cancer/software/GENE-E/index.html), and rows were clustered using the one minus Pearson correlation metric.

ChIP-qPCR. ChIP analysis was performed as described previously, with minor modifications (9). ChIPed DNA was purified using the PCR Clean-up Extraction Kit (Macherey-Nagel), after which qPCR was performed as described previously (47). Data were normalized to the input (fold differences = 2 ^ (ΔΔCt sample - ΔΔCt input)). ChIP primer sequences are listed in Supplemental Table 2. For LXR ChIP assays, an anti-LXRA antibody (Abcam, catalog ab41902) was used. For LRH-1 ChIP experiments, a custom LRH-1 antibody was generated. A synthetic peptide ([H]-QEFSNRNRQEKLSAFG-[NH2]) was used to immunize 2 rab-
bits (AbFRONTIER). The antiserum with the highest ELISA titer was selected and used in ChIP experiments. The preimmunization serum from the same rabbit was used as a negative control.

**LXR agonist treatment.** Hepa 1.6 (ATCC, catalog CRL1830) or AML1-12 (ATCC, catalog CRL2254) cells were treated with 1 μM of GW3965 (Selleckchem), a dual LXRα and LXRβ agonist, for 6 hours in full medium.

**In vivo siRNA transfection.** siRNA sequences are listed in Supplemental Table 4. HPLC-purified siRNAs (3 nmol, Microsynth) were tail-vein injected into each recipient mouse in vivo-JetPEI (Polyplus) according to the manufacturer’s instructions. Mice were fast-refed as described above and sacrificed 2 days after injection.

**Adenoviral infection.** Osbp3 cDNA was cloned into a PENTR/D-TOP plasmid (Invitrogen; the Topo primer is listed in Supplemental Table 3) and then subcloned into the pAd/CMV-DEST plasmid (Invitrogen; the Topo primer is listed in Supplemental Table 4) was engineered to create a pre-miRNA sequence targeting Osbp3, which was cloned into an AAV vector construct driven by the liver-specific hAAT promoter. AAV8 mirOsbp3 viral vectors were generated and titrated as described previously (48, 49) and injected into jugular vein under isoflurane anesthesia (5 × 1011 vg). Two weeks after the injection, mice were fasted for 24 hours followed by 6 hours refeeding, then sacrificed, and tissues were snap-frozen.

**Lipid analyses and plasma parameters.** Hepatic lipids were extracted according to the Bligh and Dyer protocol (50). Triglycerides, free fatty acids, and cholesterol contents in plasma and/or hepatic lipid fractions were quantified using enzymatic assays (Roche). To assess fatty acid synthesis rates in vivo, mice received sodium [1-13C] acetate via their drinking water (2%) 24 hours prior to sacrifice. Fatty acids derived from hepatic lipid extracts were liberated, derivatized, and subjected to gas chromatography–mass spectrometry (GC-MS) analysis in order to calculate the fractional synthesis rates from the incorporation of 13C-acetate as described previously (51). ASAT and ALAT concentrations in blood were determined using standard clinical chemistry methods.

**VLDL secretion assay and glucose-6-phosphate quantification.** The VLDL secretion assay was performed as described previously (51). Thirteen-week-old male LRH-1 K289R or LRH-1 WT mice were subjected to the fasting-refeeding protocol and treated with 50 mg/ml poloxamer 407 (Sigma-Aldrich, catalog 16758) 8 hours after refeeding was initiated. Blood samples were collected once before and every hour after poloxamer treatment to determine the triglyceride content. Glucose-6-phosphate content was determined using enzymatic assays as described previously (6).

**Immunohistochemistry.** Liver sections were cut into 5-μm-thick serial cryosections for oil red O staining to visualize neutral lipids or paraffin cryosections to stain collagen with sirius red, CD45-positive cells using rat anti-CD45 antibody (eBioscience, catalog 30-F11), or H&E.

**Statistics.** Data are expressed as mean ± SEM. Comparison of differences between 2 groups was assessed using unpaired 2-tailed Student’s t tests. Multiple group comparisons were assessed by ANOVA and Bonferroni’s post-hoc t tests. P < 0.05 was considered statistically significant.

**Study approval.** All animal procedures were approved by the Swiss authorities (Canton of Vaud, animal protocols ID 2380, 2561, and 2768) and performed in accordance with École Polytechnique Fédérale de Lausanne institutional guidelines.

**Author contributions**

SS and VL designed and carried out most of the experiments, analyzed data, prepared the figures, and wrote the manuscript. PX and DR helped with Western blotting, histology, adenovirus production, and/or in vivo experiments. HD carried out the ChIP-qPCR experiments. XW helped with bioinformatic analyses. VJ and FB designed and generated the AAV8 constructs. MHO performed GC-MS analysis and quantification of fatty acids. TFL and MHO provided useful advice on the experimental procedures. KS supervised all aspects of the work.

**Acknowledgments**

We thank Vasco de Campos and Norman Moullan for help with tail-vein and jugular-vein injections and Theo van Dijk, Theo Boer, Sara Oppi, Thiabud Clerc, Sabrina Bichet, and Soline Oudouard for technical help. This study was funded by École Polytechnique Fédérale de Lausanne and the Swiss National Science Foundation (31003A_1666995 and CRSII3_160798/1). SS was supported by postdoctoral fellowships from the German Academy of Sciences Leopoldina (LPDS 2011-6) and the Novartis Consumer Health Foundation and an Ambizione grant from the Swiss National Science Foundation (PZOPP3_161521). VL was supported by a PhD grant from the Portuguese Foundation for Science and Technology (SFRH/BD/52046/2012) through the Graduate Program in Basic and Applied Biology (GABBA) PhD program. MHO holds a Rosalind Franklin Fellowship from the University of Groningen. FB is an ICREA Academia recipient, Generalitat de Catalunya, Spain. AAV vector generation and production were funded by the Ministerio de Economía y Competitividad, Plan Nacional 1+D+1 (SAF2014-54886-R), Spain.
