Anti-self/tumor T cell function can be improved by increasing TCR-peptide MHC (pMHC) affinity within physiological limits, but paradoxically further increases ($K_d < 1 \mu M$) lead to drastic functional declines. Using human CD8+ T cells engineered with TCRs of incremental affinity for the tumor antigen HLA-A2/NY-ESO-1, we investigated the molecular mechanisms underlying this high-affinity–associated loss of function. As compared with cells expressing TCR affinities generating optimal function ($K_d = 5$ to $1 \mu M$), those with supraphysiological affinity ($K_d = 1 \mu M$ to $15 \mu M$) showed impaired gene expression, signaling, and surface expression of activatory/costimulatory receptors. Preferential expression of the inhibitory receptor programmed cell death-1 (PD-1) was limited to T cells with the highest TCR affinity, correlating with full functional recovery upon PD-1 ligand 1 (PD-L1) blockade. In contrast, upregulation of the Src homology 2 domain-containing phosphatase 1 (SHP-1/PTPN6) was broad, with gradually enhanced expression in CD8+ T cells with increasing TCR affinities. Consequently, pharmacological inhibition of SHP-1 with sodium stibogluconate augmented the function of all engineered T cells, and this correlated with the TCR affinity–dependent levels of SHP-1. These data highlight an unexpected and global role of SHP-1 in regulating CD8+ T cell activation and responsiveness and support the development of therapies inhibiting protein tyrosine phosphatases to enhance T cell–mediated immunity.

Introduction

CD8+ T cell responses rely on the specific recognition by TCRs of small immunogenic peptides presented in the context of MHC class I molecules at the surface of infected or transformed cells. Binding of TCR to peptide-MHC is characterized by relatively low molecular affinity (100 nM to 1 \mu M) and high specificity and sensitivity, thus enabling T cells to detect rare antigenic epitopes on APCs (1). Due to mechanisms of central and peripheral tolerance, circulating autoreactive T cells recognize self/tumor-associated antigens typically have TCR–pMHC affinities at the lower end of the physiological range and/or are maintained in unresponsive functional states when compared with pathogen Ag–specific T cells. This might in part explain why tumor-reactive T cell responses detected in cancer patients often fail to control or eliminate advanced disease (2).

Adoptive cell transfer (ACT) of T cells engineered to express TCRs of increased affinity for tumor antigens represents an attractive immunotherapeutic approach to inducing and boosting immune reactivity toward poor immunogenic tumors (3). Numerous studies suggest that enhancing TCR-pMHC interactions (half-life and affinity) would endow T cells with higher functional and protective capacity (4). However, it was also shown that T cells engineered with TCR of very high supraphysiological affinity for pMHC ($K_d < 1$ nM) lose antigen specificity and become cross-reactive or alloreactive (5–7). As such, TCR optimization through affinity alterations has to include the careful evaluation of optimal T cell responsiveness to ensure the safety of TCR-engineered T cells in clinical trials (3).

Recently, we characterized the functional impact of TCR-pMHC binding strength by using a panel of human CD8+ T cells engineered through structure-based rationally designed TCRs of incremental affinity for the self/tumor antigen A2/NY-ESO-1 (8–11). At low peptide dose stimulation, T cells with TCR affinities ranging in the upper physiological limit ($K_d$ from 5 \mu M to 1 \mu M) display higher biological responses, when compared with T cells expressing the WT TCR ($K_d$ at 21.4 \mu M) (11). Strikingly, tumor-reactive T cells expressing TCRs of supraphysiological affinities ($K_d$ from 1 \mu M to 15 \mu M) show drastic functional decline irrespective of CD8+ coengagement, which is not associated with loss of antigen specificity (11). Similarly, other studies reported that T cells with TCR-pMHC affinities and/or half-lives extending above the natural range exhibit attenuated T cell activation upon TCR triggering as well as impaired expansion potential and responsiveness (12–16).

To identify the molecular mechanisms underlying these functional defects, we characterized global gene expression, signaling pathways, and activatory/inhibitory membrane receptors on human CD8+ T cells engineered with TCRs of incremental affinity for HLA-A2/NY-ESO-1. We describe how the inhibitory receptor programmed cell death-1 (PD-1) and the Src homology 2 domain–containing phosphatase 1 (SHP-1) are involved in restricting T cell function in TCR-engineered CD8+ T cells. Strikingly, SHP-1 mediated a gradual functional inhibition of CD8+ T cells, along with TCR-binding affinity, independently of PD-1 involvement. Together, these data indicate that, in the context of adoptive cell therapy (ACT), TCR-mediated SHP-1 signaling may counterregulate T cell responses by limiting the potential cytotoxic effect of TCR-optimized CD8+ T cells against self/tumor antigens.
Impaired function of human primary CD8+ T cells expressing self/tumor-specific TCRs of supraphysiological affinity. Using a panel of affinity-optimized HLA-A*0201-restricted NY-ESO-1157–165-specific TCR (BC1) variants with gradually increased affinity of up to 1400-fold from the native TCR (refs. 8, 9, and Supplemental Table 1; supplemental material available online with this article; doi:10.1172/JCI65325DS1), we previously found that maximal biological activity occurred within a well-defined affinity window with \(K_d\) ranging from 5 to 1 \(\mu M\) (10, 11). Importantly, under low-peptide stimulation conditions, cellular activity, including Ca2+ mobilization capacity (Figure 1A) and tumor cell killing (Figure 1B), was globally attenuated for T cells expressing either TCRs of very low (\(K_d > 100 \mu M\); V491) or of supraphysiological (\(K_d < 1 \mu M\); TM\(\alpha\), QM\(\alpha\), and wtc51m) affinities. Conversely, high concentrations of NY-ESO-1157–165 peptide loaded on APCs restored the Ca2+ mobilization capacity of CD8+ T cells with supraphysiological TCRs (Supplemental Figure 1), consistent with our recent report (11). Similar data were obtained independently of stimulation with peptide-pulsed APCs or A2/peptide multimers. This functional decline was not caused by lower TCR expression, as engineered CD8+ T cells and \(\alpha\)-TCR knockout SUP-T1 cells expressed comparable surface levels of TCR-\(\alpha\)β chains (Figure 1C and Supplemental Figure 2A). Upon short-term peptide stimulation, we observed substantial TCR downregulation (reduced multimer fluorescence; Figure 1E) in all engineered CD8+ T cells independently of their TCR affinities (e.g., optimal versus supraphysiological). TCR downmodula-
tion was assessed either by multimer fluorescence (Figure 1E) or by staining with anti-BV13 mAbs (Supplemental Figure 2). In contrast, reduced CD8 coreceptor expression (Figure 1D and Supplemental Figure 2) was primarily found in T cells expressing TCRs mediating maximal/optimal function (A97L, DMβ, TMβ) rather than in T cells of supraphysiological TCR affinity (TMα, wtc51m). Altogether, our data further emphasize the paradoxical status of these NY-ESO-1–specific T cells expressing very high TCR affinities with impaired functionality despite retaining robust surface-binding TCR avidity and TCR downregulation capacity upon stimulation (Figure 1 and refs. 10, 11). These findings suggest the presence of potential mechanisms controlling T cell activation, signaling, and subsequent functionality.

Altered gene expression profiles in CD8+ T cells with TCRs of supraphysiological affinity following antigen-specific stimulation. In order to uncover the molecular mechanisms involved in the impaired functional responsiveness of cells bearing supraphysiological TCRs, we performed a genome-wide microarray analysis on primary CD8+ T cells expressing the panel of TCR variants following low-dose A2/NY-ESO-1–specific multimer stimulation (Figure 2A). We compared the global gene expression levels of all samples before and after 6 hours of stimulation (names depicted in red) cluster together within the unstimulated (0 hour) profile 1 group. (B) 524 genes enriched between 0 and 6 hours in T cells transduced with TCRs giving maximal function (G50A, A97L, DMβ, TMβ) could be classified using GOTermFinder. (C) Log2-fold changes in the expression levels of representative TCR response genes (CRTAM, IL2RA, T cell effector cytokine (IFNG), and costimulatory molecules (TNFRSF18 [GITR], TNFRSF4 [OX40], TNFRSF9 [4-1BB])).
identified 524 differentially expressed genes and classified them according to 6 general Gene Ontology (GO) terms. The average absolute log2 fold change (0 to 6 hours) of the genes within each GO term is represented in Figure 2B. Remarkably, all GO terms (immune response, T cell activation, cell proliferation, signaling, gene expression, and apoptosis) had the same overall outline demonstrating a drastic underrepresentation of the gene expression within V49I and wtc51m TCR variants. The average absolute fold change was progressively increased from low to optimal TCR affinity before declining in T cells with supraphysiological TCR variants (TMα and wtc51m). Interestingly, the pattern of gene expression profile related to apoptosis strongly correlated to the one observed following A2/peptide multimer stimulation and staining with Annexin V (11), with highest levels of apoptosis for CD8+ T cells expressing optimal TCRs. In addition, several key genes involved in T cell activation (e.g., CRTAM, IFNG, and IL2RA) as well as costimulatory molecules (e.g., TNFRSF18, TNFRSF4, TNFRSF9) showed a 2-fold or greater change and displayed the same overall bell-shape profile following 6-hour stimulation (Figure 2C).

No major changes in genes classified to the GO terms were observed at baseline in unstimulated CD8+ T cells (Supplemental Figure 3).

Similar to the functional data (Figure 1), gene expression analyses revealed that T cells engineered with TCR of infra- or supraphysiological affinity clustered together and failed to properly modulate their transcriptome upon specific TCR triggering. Conversely, the transcriptional gene signatures of CD8+ T cells expressing optimal TCR variants (G50A, A97L, DMβ, and TMβ) revealed drastic global changes (up- or downregulation) in gene expression levels following short-term antigen-specific stimulation, supporting enhanced T cell responsiveness.

Affinity of TCR-pMHC interaction affects the intensity and duration of TCR-mediated intracellular signaling. To gain functional insights into the molecular mechanisms underlying altered gene expression profiling associated with very low or very high TCR affinities (Figure 2), we explored the impact of TCR affinity on cell signaling. We assessed the activation levels of ZAP-70, a proximal activatory molecule of TCR signaling and of the distal MAPK family members ERK1/2 (p38). SUP-T1 and CD8+ T cells expressing TCR variants were stimulated with A2/NY-ESO-1-specific multimers and levels of phosphorylated ZAP-70 (pY319) and ERK1/2 (pT202/pY204 ERK1; pT185/pY187 ERK2) were quantified in kinetic analyses. Upon specific stimulation, we found differential levels of ZAP-70 phosphorylation intensity and duration correlating with TCR affinity variants (Figure 3 and Supplemental Figure 4). V49I-transduced T cells showed only transient and low levels of ZAP-70 phosphorylation, whereas cells expressing optimal functions (e.g., A97L, DMβ) generated fast and sustained ZAP-70 phosphorylation. Importantly, in CD8+ (Figure 3C and Supplemental Figure 4) and SUP-T1 (Figure 3, A and B) cells expressing supraphysiological TCR affinities (e.g., QMα and wtc51m), ZAP-70 phosphorylation declined rapidly and substantially following specific stimulation.
ERK1/2 phosphorylation profiles corresponded with those observed for ZAP-70 phosphorylation, with an overall increase in the signaling intensities depending as well on the TCR affinity variants. Maximal phosphorylation was found for TCR variants of optimal function, while T cells with supraphysiological TCRs showed mostly a transient and rapid loss of ERK1/2 phosphorylation following TCR stimulation (Figure 3 and Supplemental Figure 4). Together, the transgenic TCR affinity strongly affected both the intensity and the duration of ZAP-70 and ERK1/2 phosphorylation. Importantly, CD8^+ T cells expressing supraphysiological TCR affinity presented a drastically reduced activation of key TCR downstream signaling pathways (Ca^{2+} and MAPK), and this occurred at a very proximal step in the TCR-signaling cascade (ZAP-70). Conversely, the low cell signaling observed in V49I-expressing T cells nicely correlated with the poor intrinsic binding avidity of this particular TCR (10, 11).

Impact of TCR-pMHC affinity on the expression of costimulatory/inhibitory receptors. Since global genome profiling revealed reduced expression of genes involved in costimulatory/activatory molecules in supraphysiological T cells (Figure 2), we next focused on measuring the surface expression levels of CD28 as well as CD27 and HVEM and their respective ligands (CD70 and BTLA) (Figure 4A). Under steady-state conditions, most of the TCR-transduced CD8^+ T cells, including cells with the lowest TCR affinity variant (V49I), expressed similar levels of CD28 as well as of CD27 and HVEM with their respective ligands. Strikingly, T cells bearing supraphysiological TCR affinity (wtc51m) had substantially lower expression of CD28, HVEM, and CD70, all 3 involved in T cell activation signal. In contrast, BTLA, known to inhibit T cell function (17), was expressed at the highest levels in wtc51m-expressing T cells (Figure 4A). No significant differences in CD8ε expression were found (data not shown), yet there was a trend of lower expression of CD8β in T cells with supraphysiological TCRs (Figure 4A). Significantly reduced expression of Granzyme B and Perforin (Figure 4B) was also found in the latter T cells (wtc51m), consistent with their attenuated killing capacities (Figure 1B). Importantly, similar data were obtained when CD8^+ T cells were stimulated with A2/NY-ESO-1–specific multimers over a 24-hour and 48-hour period of time (data not shown). Overall, these data further support the notion that CD8^+ T cells expressing supraphysiological TCR affinities likely exhibit molecular mechanisms that actively downregulate surface coactivatory molecules/receptors. This was readily observed under steady-state conditions.

Engineered T cells of supraphysiological TCR affinity show enhanced expression of PD-1 correlating with full functional recovery upon PD-L1 blockade. CD8^+ T cells express multiple negative regulators, such as BTLA, PD-1, and CTLA-4, which have been proposed to play central roles in preventing uncontrolled T cell activation and autoimmunity during inflammatory responses (18). Therefore, we sought to determine whether PD-1 could functionally regulate CD8^+ T cells expressing TCRs of increased affinities. We assessed PD-1 expression in unstimulated TCR-engineered T cells (Figure 5, B and C). Comparable with mRNA data (Figure 5A), elevated PD-1 levels were exclusively found in CD8^+ T cells of highest supraphysiological affinity (wtc51m). Of note, PD1 mRNA fold-change at 6-hour PD1 expression was highly comparable across wtc51m-expressing T cells mediating optimal function (A97L, DMβ, and TMβ), thereby indicating that PD-1 expression can also be induced shortly after antigen-specific TCR stimulation (Figure 5A). No significant differences were found in expression levels of PD-1 ligand 1 (PD-L1) (Figure 5B) and CTLA-4 (data not shown).

Since PD-L1 surface expression was highly comparable across the TCR affinity panel, we next evaluated the biological significance of PD-1 expression on T cell responsiveness by blocking PD-1/PD-L1 interaction. All transduced CD8^+ T cells were incubated with PD-L1 neutralizing antibody prior to LAMP1/CD107a degranulation assays (Figure 5, D and E). After 4-hour triggering with the NY-ESO-1 peptide, PD-L1 blockade had no effect on CD107a degranulation in most of CD8^+ T cells, with the exception of the supraphysiological TCR variant (wtc51m), which exhibited an increased proportion of degranulating cells, even reaching lev...
Figure 5
PD-1 expression in TCR-engineered CD8+ T cells and functional impact of PD-L1 blockade. (A) Unstimulated at baseline (0 hour) and log2 fold change (0–6 hours) expression levels of PD1 transcripts as detected in microarray analysis. (B) Average surface expression of PD-1 (n > 9 independent experiments) and its ligand PD-L1 (n > 6 independent experiments) of TCR-engineered CD8+ T cells. Unpaired 2-tailed t test; ***P < 0.001; **P < 0.01. (C) Representative histograms of PD-1 surface expression (in MFI) in TCR-engineered CD8+ T cells under steady-state conditions. (D) Representative histograms of levels (in MFI) of the degranulation marker LAMP-1/CD107a in TCR-transduced CD8+ T cells without (control, blue histograms) or with PD-L1 blocking antibody (red histograms) prior to 4-hour stimulation with 10 μM NY-ESO-1157–165–loaded T2 cells. CD107a degranulation following stimulation with unloaded T2 cells is depicted as gray histograms. Graphs below each respective histogram represent the direct comparison of TCR stimulation–associated CD107a levels without (–) or with PD-L1 blockade (+). Data were obtained from more than 4 independent experiments. Paired 2-tailed t test, **P < 0.01. (E) Relative CD107a degranulation ratio (in gMFI) obtained in the presence versus the absence of PD-L1 blocking antibody. Graphs are depicted as relative CD107 fold increase following stimulation with unloaded (left panel) or NY-ESO-1–pulsed (right panel) T2 cells. Unpaired 2-tailed t test; **P < 0.01; *P < 0.05.
Enhanced expression of SHP-1 phosphatase in a TCR affinity–dependent manner. SHP-1 and SHP-2 phosphatases can be recruited by multiple inhibitory surface receptors in T cells and may inhibit TCR signaling (19) through dephosphorylation of proximal signaling targets (e.g., LCK, ZAP-70, CD3ζ). Under unstimulated conditions, SHP1 gene expression was progressively increased from low to high TCR affinity (Figure 6A; baseline). We characterized the expression levels of total SHP-1 protein and its phosphorylated activatory form Y536 (20) as well as those of total SHP-2 protein (Figure 6 and Supplemental Figure 5). Maximum levels of SHP-1 phosphorylation were detected in both CD8+ and SUP-T1 T cells transduced with supraphysiological TCR variants (e.g., QM5 and wtc51m) after antigen-specific stimulation and already under steady-state conditions. Importantly, transient levels of phosphorylated SHP-1 were also enhanced in the other TCR variants upon stimulation, yet never reached those observed in QM5- and wtc51m-transduced T cells. Total SHP-1 protein revealed expression patterns that followed the same TCR binding hierarchy, with intermediate and highest levels found for optimal and supraphysiological TCR affinities, respectively (Figure 6). In CD8+ T cells, the weak binding TCR ligand V49I was also able to trigger SHP-1 protein expression and phosphorylation, consistent with a previous report (21) showing that SHP-1 is involved in antagonist-mediated inhibition. Thus, differing from PD-1 expression, SHP-1 phosphatase was found upregulated in a TCR affinity–dependent manner with substantial expression levels readily found in T cells of optimal TCR affinities. A comparable trend was observed for total SHP-2 expression (Supplemental Figure 5).

Finally, we assessed the expression levels of miR-181a and miR-155 (Figure 6E), 2 microRNAs, mostly known to affect, respectively, lymphocyte development and function (22, 23). Following specific TCR stimulation, only minor changes in miR-181a expression were found within the engineered panels of CD8+ T cells. This highly contrasted with the strong induction in pri-miR-155 (BIC transcript) and miR-155 expression observed within T cells expressing WT and optimal TCR affinities (e.g., A97L, DMβ).

Impact of pharmacological SHP-1 phosphatase inhibition on degranulation and cytotoxicity of TCR engineered CD8+ T cells. Sodium stibogluconate (SSG) is widely used to treat visceral leishmaniasis and was recently identified as an important clinically suitable protein tyrosine phosphatase inhibitor in cancer patients (24, 25). Notably, SSG has been shown to selectively inhibit protein tyrosine phosphatases, among which SHP-1 was the most sensitive (26). Given the elevated levels of SHP-1 and SHP-2 protein expression within engineered CD8+ T cells, we next determined whether SSG treatment might improve their function, irrespectively of PD-1 expression (Figure 7). We incubated the CD8+ T cells in the presence or absence of SSG for 3 days at a concentration (50 μg/ml) shown to partially inhibit SHP-2 activity as well (26). Following pharmacological inhibition of SHP-1/SHP-2, increased degranulation potential (Figure 7, A and B) was found within the whole T cell panel, except for cells expressing the infraphysiological TCR affinity V49I. Importantly, functional recovery was further validated in target cell killing experiments (Figure 7, C and D) and correlated well with the affinity-dependent levels of SHP-1 phosphatase found in T cells. Indeed, and in agreement with their stronger phosphorylation levels, supraphysiological T cells showed better killing recovery capacity when compared with WT and optimal T cells. Although we cannot formally exclude off-target effects of SSG treatment, these results support the notion that SHP-1 phosphatase (and eventually SHP-2) may mediate a gradual functional inhibition in TCR-engineered CD8+ T cells depending on TCR affinity, but not necessarily on the degree of PD-1 involvement.

Discussion

The panel of rationally designed NY-ESO-1157–165–specific TCRs with incremental affinity (8, 9) provides a unique model for investigating the relationship between TCR affinity and T cell function as well as its modulation by activatory/inhibitory coreceptors and their signaling pathways. Here, we show that the impaired functionality recently observed in CD8+ T cells engineered with supraphysiological TCR affinities (Kd < 1 μM) (11) was associated with a strong decrease in overall gene expression profile, intracellular signaling, and surface expression of activatory TNFR superfamily members (Figures 2, 3, and 4). Our major findings revealed that the T cell effectiveness of engineered CD8+ T cells was limited by at least 2 mechanisms. The first one was characterized by the preferential expression of PD-1 inhibitory receptor within T cells of highest supraphysiological TCR affinity (wtc51m variant), and this correlated in those cells with restored cell responsiveness upon PD-1/PD-L1 blockade (Figure 5). The second one was associated with the gradual increased expression of SHP-1 phosphatase in a TCR affinity-dependent manner, from WT to very high TCR affinities (Figure 6). In contrast to PD-1/PD-L1 blockade experiments, pharmacological inhibition using SSG known to inhibit SHP-1 (and partially SHP-2) allowed further incremental gaining of cell function in engineered CD8+ T cells according to their TCR-binding affinity (Figure 7).

ACT using autologous T lymphocytes reprogrammed by TCR gene transfer aims to confer robust immune reactivity toward defined tumor-associated antigen-bearing cells to which the endogenous T cell repertoire is weak or nonresponsive. Recently, 2 clinical trials were conducted whereby autologous T cells transduced with affinity-enhanced TCRs specific for tumor-associated antigens were adoptively transferred to patients with metastatic melanoma or sarcoma and demonstrated objective clinical responses (27, 28). Robbins and colleagues (28) were the first to examine the in vivo efficacy of adoptively transferred autologous T cells transduced with the sequence-optimized IG4 TCR specific for NY-ESO-1 (15). This genetically modified TCR possesses an affinity that lies just beyond the natural affinity range and confers maximal in vitro functionality with lowest cross-reactivity (6). In line with these observations, vaccination with peptide ligands of intermediate affinity yielded the most potent tumor-reactive CD8+ T cells in vivo and best tumor growth control in BALB/c mice (15). Recently, Corse et al. further confirmed that peptide binding to the TCR with medium strength induced optimal in vivo CD4+ T cell activation and subsequent immune responses (12). Future directions involve integrating the vast knowledge acquired from the in vivo experimental studies into the context of in vivo immune responses and clinical trials of ACT (reviewed in ref. 29).

The in silico structure-based approach allowed us to rationally design sequence substitutions in the CDR2e and/or CDR2β and/or CDR3β loops, known to interact either with the MHC surface or the bound peptide (Supplemental Table 1, refs. 8, 9; V. Zoete, M. Irving, and O. Michielin, unpublished observations). We also included in this panel the supraphysiological TCR variant wtc51m, previously identified by phage-display screening, with nanomolar range of affinity to the HLA-A2/NY-ESO-1 complex (30). Importantly, and despite their impaired functionality, all engineered CD8+ T cells expressing supraphysiological TCRs of $K_D < 1 \mu M$ (TMα, QMα, and wtc51m) retained a high degree of specificity toward the cognate pMHC target in functional assays (10, 11). An important finding in our study is that only engineered T cells with the highest TCR affinity variant (wtc51m) upregulated inhibitory receptors (PD-1 and BTLA) and conversely downregulated coactivatory receptors (CD28, HVEM, CD8β) (Figures 4 and 5). What remains intriguing is how such affinity T cells control the expression of their activatory/inhibitory receptors readily under steady-state settings. One likely explanation is that, in contrast with the rational design approach (refs. 8, 9; V. Zoete, M. Irving, and O. Michielin, unpublished observations), gain in affinity for the wtc51m TCR variant resulted from multiple increased interac-
tions with the HLA-A2 molecule, as this particular TCR contained the wtc51m TCR variant resulted from multiple increased interactions with the HLA-A2 molecule, as this particular TCR contained

SHP-1 was found upregulated in a TCR affinity–dependent manner, with the highest levels in T cells with supraphysiological TCRs (Figure 6 and Supplemental Figure 5). This suggests that SHP-1 may play a dual role and restrict not only T cell signaling at the very low range of TCR stimulation (e.g., with antagonist ligands) as previously described (21), but also at the higher range (e.g., with optimized and supraphysiological TCR affinity ligands). Our observations are further consistent with a recent study showing that B cell receptor (BCR) signaling was limited by SHP-1 activity in the most proliferating germinal center B cells, revealing a regulatory effect on the affinity-based selection of those cells (41). However, additional studies using SHP-1–specific siRNA are still needed to fully demonstrate the impact of SHP-1 in mediating functional inhibition of affinity-optimized T cells.

Specific microRNAs have been shown to be critical for T cell development and function. For instance, transcriptional activation of miR-155 is detectable upon lymphocyte activation (42) and correlates with increased expression in human antigen-experienced CD8\(^+\) T cell subsets (23). Here, we provide evidence that miR-155 expression, but paradoxically not miR-181a expression, may be involved in modulating T cell function in TCR affinity–optimized CD8\(^+\) T cells. Thus, it will be of great importance to further explore the mechanisms by which miR-155 may influence cell activation and responsiveness along the TCR affinity range in peripheral T lymphocytes.

CTLA-4 and PD-1 are 2 checkpoint inhibitory receptors that have become novel targets for treating cancer patients, as these molecules can be specifically blocked with antibodies (43). Consequently, antibodies against PD-1 and PD-L1 have entered phase 1 clinical trials, and initial results showing objective tumor regression are promising along the TCR affinity range in peripheral T lymphocytes. CTLA-4 and PD-1 are 2 checkpoint inhibitory receptors that have become novel targets for treating cancer patients, as these molecules can be specifically blocked with antibodies (43). Consequently, antibodies against PD-1 and PD-L1 have entered phase 1 clinical trials, and initial results showing objective tumor regression are promising along the TCR affinity range in peripheral T lymphocytes.

**Methods**

**Cell lines and primary CD8\(^+\) T cells.** TCR-α knockout SUP-T1 cells and HLA-A2\(^+\)/TAP-deficient T2 cells were cultured in RPMI supplemented with 10% FCS, 10 mM Hepes, penicillin (100 U/ml), and streptomycin (100 μg/ml). Human primary HLA-A2\(^+\)/CD8\(^+\) T lymphocytes were obtained following positive enrichment using anti-CD8–coated magnetic microbeads (Miltenyi Biotec) and cultured in RPMI supplemented with 8% HS and 150 U/ml recombinant human IL-2. Cell-surface analysis and functional assays were performed between day 10 and 15 after stimulation with 30-Gy irradiated PBMCs as feeder cells and 1 μM PHA (Oxoid) as described previously (10).

**NY-ESO-1–specific TCR constructs, lentiviral production, and cell transduction.** Cloning strategies and lentiviral production were performed as described previously (10, 11). The full-length codon-optimized TCR AV23.1 and TCR BV13.1 chain sequences of a dominant NY-ESO-1\(^{157-165}\)–specific T cell clone of patient LAU 155 were cloned in the pRRL, third generation lentiviral vectors, as an HPGK-AV23.1-IRES-BV13.1 construct. Structure-based amino acid substitutions were introduced into the WT TCR sequence (Figure 6 and Supplemental Figure 5). This suggests that SHP-1 may play a dual role and restrict not only T cell signaling at the very low range of TCR stimulation (e.g., with antagonist ligands) as previously described (21), but also at the higher range (e.g., with optimized and supraphysiological TCR affinity ligands). Our observations are further consistent with a recent study showing that B cell receptor (BCR) signaling was limited by SHP-1 activity in the most proliferating germinal center B cells, revealing a regulatory effect on the affinity-based selection of those cells (41). However, additional studies using SHP-1–specific siRNA are still needed to fully demonstrate the impact of SHP-1 in mediating functional inhibition of affinity-optimized T cells.

Specific microRNAs have been shown to be critical for T cell development and function. For instance, transcriptional activation of miR-155 is detectable upon lymphocyte activation (42) and correlates with increased expression in human antigen-experienced CD8\(^+\) T cell subsets (23). Here, we provide evidence that miR-155 expression, but paradoxically not miR-181a expression, may be involved in modulating T cell function in TCR affinity–optimized CD8\(^+\) T cells. Thus, it will be of great importance to further explore the mechanisms by which miR-155 may influence cell activation and responsiveness along the TCR affinity range in peripheral T lymphocytes.

CTLA-4 and PD-1 are 2 checkpoint inhibitory receptors that have become novel targets for treating cancer patients, as these molecules can be specifically blocked with antibodies (43). Consequently, antibodies against PD-1 and PD-L1 have entered phase 1 clinical trials, and initial results showing objective tumor regression are promising along the TCR affinity range in peripheral T lymphocytes. CTLA-4 and PD-1 are 2 checkpoint inhibitory receptors that have become novel targets for treating cancer patients, as these molecules can be specifically blocked with antibodies (43). Consequently, antibodies against PD-1 and PD-L1 have entered phase 1 clinical trials, and initial results showing objective tumor regression are promising along the TCR affinity range in peripheral T lymphocytes.
(Tyr319)/Sryk(Tyr352), rabbit anti–ZAP-70 (99F2) (Cell Signaling Technology), rabbit anti–pSHP-1 (Tyr356) (ECM Biosciences), mouse anti–α-tubulin (B-5-1-2) (Sigma-Aldrich), and rabbit anti-actin (AA20-33) (Sigma-Aldrich). Quantification of specific bands was done using Phospholmager software (ImageJ) and normalized to α-tubulin or actin expression levels.

Quantitative PCR analysis for mir-155 and mir-181A expression. TCR-transduced CD8+ T cells (1 x 10^6) were left either unstimulated (baseline, 0 hour) or stimulated with 0.01 μg/ml unlabelled A2/NY-ESO-1 179-185 multimers for 6, 24, and 48 hours at 37°C under 10 μl rHL-2 medium conditions. Following incubation, cells were washed and total RNA was extracted with the miRNA Kit (Ambion; Life Technologies), and mature microRNAs (hsa-miR-155, hsa-miR-181a, and hsa-RNU48) were reverse transcribed with the TaqMan MicroRNA Reverse Transcription Kit (Applied Biosystems). Amplification and real-time acquisition were performed using Universal PCR Master Mix (Applied Biosystems) in MicroAmp 384-well plates (Applied Biosystems) on a LightCycler 480 instrument (Roche Ltd.). Ct (RNU48) was subtracted from Ct (mir-155, mir-181A) to calculate relative expression (ΔCt).

Functional PD-L1 blockade or pharmacological SHP-1/SHP-2 inhibition assays. For PD-L1 blockade, 5 x 10^5 TCR-transduced CD8+ T cells were cultured in 300 μl RPMI complemented with 8% HS, 150 μl rHL-2 at 37°C without (control) or with 5 μg/ml PD-L1 blocking antibody (CD274 clone MHI1, eBioscience). Alternatively, 50 μg/ml SSG (Subvent, China; Santa Cruz Biotechnology Inc.) was used for SHP-1/SHP-2 inhibition. After 3 days, 4 x 10^5 T cells were incubated at 37°C for 4 hours with 2 x 10^5 either unloaded T2 control or 10 μg/ml NY-ESO-1-loaded T2 cells (E:T ratio 2:1) together with PE-Cy5 CD107a/LAMP-1 (BD Biosciences) antibody. Acquisition was performed on an LSRI (BD Biosciences) or a Gallios (Beckman Coulter) instrument, and data were analyzed with FlowJo (TreeStar). For target cell killing experiments, TCR-transduced CD8+ T cells were incubated with 50 μg/ml SSG for 3–4 days as described above before assessing antigen-specific lytic activity in a 4-hour 51Cr-release assay against ME275 cells (HLA-A2–/NY-ESO-1–) at 10:1 and 3:1 effector/target (E:T) ratios.

Acknowledgments
We gratefully acknowledge J. Dudda, P. Guillaume, M. Irving, I. Luescher, R. Perret, B. Salaun, and V. Zoete for essential contributions and advice. We are also thankful for the excellent help of N. Montandon, and M. van Overloop. We thank P.O. Gannon for critical reading of the manuscript. This study was sponsored and supported by the Swiss National Center of Competence in Research (NCCR) Molecular Oncology, the Ludwig Institute for Cancer Research (New York, New York, USA), and the Swiss Cancer League (grant KLS 2635-08-2010).
