P2Y$_2$ and G$_q$/G$_{11}$ control blood pressure by mediating endothelial mechanotransduction

Elevated blood pressure is a key risk factor for developing cardiovascular diseases. Blood pressure is largely determined by vasodilatory mediators, such as nitric oxide (NO), that are released from the endothelium in response to fluid shear stress exerted by the flowing blood. Previous work has identified several mechanotransduction signaling processes that are involved in fluid shear stress–induced endothelial effects, but how fluid shear stress initiates the response is poorly understood.

Here, we evaluated human and bovine endothelial cells and found that the purinergic receptor P2Y$_2$ and the G proteins G$_q$/G$_{11}$ mediate fluid shear stress–induced endothelial responses, including [Ca$^{2+}$]$_i$ transients, activation of the endothelial NO synthase (eNOS), phosphorylation of PECAM-1 and VEGFR-2, as well as activation of SRC and AKT. In response to fluid shear stress, endothelial cells released ATP, which activates the purinergic P2Y$_2$ receptor. Mice with induced endothelium-specific P2Y$_2$, or G$_q$/G$_{11}$, deficiency lacked flow-induced vasodilatation and developed hypertension that was accompanied by reduced eNOS activation. Together, our data identify P2Y$_2$ and G$_q$/G$_{11}$ as a critical endothelial mechanosignaling pathway that is upstream of previously described mechanotransduction processes and demonstrate that P2Y$_2$ and G$_q$/G$_{11}$ are required for basal endothelial NO formation, vascular tone, and blood pressure.

Introduction

Hypertension is a primary risk factor for cardiovascular diseases including myocardial infarction and stroke (1, 2). Vascular tone and blood pressure are controlled under physiological and pathophysiological conditions by various autoregulatory functions of blood vessels. One of the fundamental autoregulatory processes that adapts vessel diameter to blood flow and critically contributes to vascular tone and blood pressure is the flow-induced relaxation of vascular smooth muscle (3). In response to fluid shear stress, the vascular endothelium releases a variety of vasoactive factors (4, 5). Of these, nitric oxide (NO) produced by endothelial NO synthase (eNOS), phosphorylation of PECAM-1 and VEGFR-2, as well as activation of SRC and AKT. In response to fluid shear stress, endothelial cells released ATP, which activates the purinergic P2Y$_2$ receptor. Mice with induced endothelium-specific P2Y$_2$, or G$_q$/G$_{11}$, deficiency lacked flow-induced vasodilatation and developed hypertension that was accompanied by reduced eNOS activation. Together, our data identify P2Y$_2$ and G$_q$/G$_{11}$ as a critical endothelial mechanosignaling pathway that is upstream of previously described mechanotransduction processes and demonstrate that P2Y$_2$ and G$_q$/G$_{11}$ are required for basal endothelial NO formation, vascular tone, and blood pressure.

Results

G$_q$/G$_{11}$ mediate endothelial response to fluid shear stress in vitro. To test the role of the heterotrimeric G proteins G$_q$ and G$_{11}$ in fluid
shear stress–induced endothelial responses, we determined the effect of siRNA-mediated knockdown of the α subunits of Gaq and Gas, Gaq and Gas, on shear stress–induced cellular effects in HUVECs and bovine aortic endothelial cells (BAECs). Suppression of Gaq/Gas expression strongly reduced shear stress–induced increases in [Ca²⁺]i (Figure 1A). It also reduced thrombin-induced effects, but had no effect on ionomycin-induced increases in [Ca²⁺]i (Figure 1A), (Supplemental Figure 1, A and B). Similarly, knockdown of Gaq/Gas, strongly reduced phosphorylation of AKT (at serine 473) and eNOS (at serine 1177 and serine 1179) induced by laminar flow in HUVECs and BAECs, respectively (Figure 1B). The same result was found after an acute increase in flow (Supplemental Figure 1C). Also, the effect of carbachol, which activates Gq/G11-coupled muscarinic receptors, on eNOS and AKT phosphorylation was prevented after knockdown of Gaq/Gas expression. However, the effect of insulin, which acts independently of Gq/G11, was unaffected (Supplemental Figure 1D), indicating that the cells had not lost the ability to respond to all stimuli. Loss of flow-induced effects
Endothelial G<sub>q</sub>/G<sub>11</sub> deficiency results in loss of flow-induced vasodilation and hypertension. To test the physiological relevance of G<sub>q</sub>/G<sub>11</sub> in endothelial flow sensing, we determined the flow-induced vasodilation of murine mesenteric arteries. In precontracted vessels isolated from inducible endothelium–specific G<sub>q</sub>/G<sub>11</sub>-deficient mice (Tie2-CreERT<sup>2</sup> Gnaq<sup>fl/fl</sup>Gna11<sup>−/−</sup>), herein referred to as EC-q/11–KO) (31), dilation in response to flow was almost completely lost (Figure 2A). Also, acetylcholine-induced (ACh-induced) vasodilation, which is mediated by the G<sub>q</sub>/G<sub>11</sub>-coupled muscarinic M3 receptor (32), was strongly inhibited (Figure 2B). However, vessels from EC-q/11–KO mice were fully responsive to the endothelium-independent vasodilator sodium nitroprusside (SNP) and the vasoconstrictor phenylephrine (Figure 2B), indicating that contractile and vasodilatory functions, per se, were not affected.

Flow-induced vasodilation is regarded as a basic mechanism critically contributing to vascular tone and basal blood pressure (29). While treatment of WT mice with tamoxifen had only a small, transient effect on mean arterial blood pressure, the induction of endothelial G<sub>q</sub>/G<sub>11</sub> deficiency in EC-q/11–KO mice by tamoxifen (31) resulted in a significant increase of approximately 20 mmHg within a few days (Figure 3A). The development of hypertension was paralleled by a decrease in plasma nitrate levels (Figure 3B) as well as by the attenuated phosphorylation of the murine mesenteric artery eNOS at serine 1176 (Figure 3C). This indicates that acute loss of endothelial G<sub>q</sub>/G<sub>11</sub>-mediated signaling strongly reduces eNOS activity in vivo, resulting in reduced NO formation, increased vascular tone, and arterial hypertension.

As shown previously, the ligation of the external carotid artery results within 2 weeks in a reduced diameter of the common carotid artery (33, 34). This process is believed to depend on endothelial flow sensing and is strongly inhibited in mice lacking eNOS (33). Consistent with an eNOS-mediated role of endothelial G<sub>q</sub>/G<sub>11</sub>...
Figure 3. Induction of endothelial Gq/G11 deficiency results in reduced eNOS activation and hypertension. (A) Telemetrically recorded blood pressure in WT (n = 9) and EC-q/11-KO (n = 8) mice before, during, and after administration of tamoxifen for 5 days. Average blood pressure 5 days before induction was set to 100%. Graphs show systolic and diastolic arterial blood pressure 4 days before tamoxifen treatment and in the second week after induction. (B) Plasma nitrate levels in WT (n = 12) and EC-q/11-KO mice (n = 12) before and 10 days after induction. (C) Phosphorylation of eNOS at serine 1176 in lysates from mesenteric arteries prepared before (-) or 3 days after (+) tamoxifen induction in WT and EC-q/11-KO. Graph shows the densitometric evaluation (n = 4). Data represent the mean ± SEM; **P ≤ 0.01 and ***P ≤ 0.001, by 2-tailed Student’s t test.

in flow-mediated remodeling, we found that the diameter of the common carotid artery did not significantly change in response to ligation of the external carotid artery in EC-q/11-KO mice compared with WT animals (Supplemental Figure 2A). EC-q/11-KO mice also showed a strong reduction in neointima formation after ligation of the common carotid artery (Supplemental Figure 2B). These data indicate that endothelial Gq/G11-mediated signaling is also required for flow-mediated vascular remodeling.

P2Y2 mediates endothelial fluid shear stress response and controls vascular tone and blood pressure. To identify potential GPCRs operating upstream of Gq/G11, we analyzed the expression of GPCRs in HUVECs and human umbilical artery endothelial cells (HUAEcs) and performed an siRNA-mediated knockdown of 42 receptors expressed in both cell types (Supplemental Figure 3, A and B). Knockdown of the purinergic P2Y2 receptor had by far the strongest effect on fluid shear stress–induced AKT phosphorylation in HUVECs (Supplemental Figure 3, B and C). P2Y2 is a Gq/G11-coupled receptor activated by ATP and uridine triphosphate (UTP) (35), and an alternative siRNA directed against P2Y2 was able to almost completely abrogate flow-induced Ca2+ transients (Figure 4A) as well as Ca2+ transients induced by the P2Y2 agonists ATP and UTP (Supplemental Figure 4A). Also, flow-induced AKT and eNOS phosphorylation, as well as tyrosine phosphorylation of SRC kinase, PECAM-1, and VEGFR-2, were strongly reduced by the knockdown of P2Y2 (Figure 4B). Similarly, the P2Y2 receptor antagonist AR-C118925 blocked fluid shear stress–induced AKT and eNOS phosphorylation (Figure 4C), whereas knockdown of the main endothelial ionotropic purinergic receptor P2X4 had no effect (Supplemental Figure 4B). Knockdown of P2Y2 also strongly reduced shear stress–induced increases in nitrate levels in cell supernatants (Figure 4D) and blocked ATP-induced, but not insulin-induced, AKT and eNOS phosphorylation (Supplemental Figure 4C). The expression of various genes encoding proteins involved in cellular signaling or flow sensing was not affected by knockdown of P2Y2 (Supplemental Figure 4D). Consistent with previous data (36–39), we found that fluid shear stress induced the release of considerable amounts of ATP from endothelial cells (Figure 4E). Interestingly, flow- but not insulin-induced AKT and eNOS phosphorylation was strongly reduced when ATP in the medium was degraded by apyrase (Figure 4, F and G), and apyrase also inhibited flow-induced NO formation (Figure 4H).
The Journal of Clinical Investigation

The influence of fluid shear stress exerted by flowing blood, the endothelium releases vasodilatory factors such as NO, which are important determinants of blood pressure under normal conditions as well as in hypertension. Previous work has identified several mechanotransduction signaling processes involved in the regulation of NO formation, vascular tone, and blood pressure.

**Discussion**

Under the influence of fluid shear stress exerted by flowing blood, the endothelium releases vasodilatory factors such as NO, which are important determinants of blood pressure under normal conditions as well as in hypertension. Previous work has identified several mechanotransduction signaling processes involved in...
fluid shear stress–induced endothelial effects (29, 30), but how fluid shear stress initiates these responses is poorly understood. Here, we show that the endothelial P2Y2 receptor and G\(\alpha_q/G\alpha_{11}\) are required to activate the mechanosensory complex consisting of PECAM-1, VE-cadherin, and VEGFR-2 in response to fluid shear stress, a process likely to involve SRC kinases, which are rapidly activated by fluid shear stress in a G\(\alpha_q/G\alpha_{11}\)-dependent manner. In contrast to independent studies (27, 28), we could not detect any direct interaction between G\(\alpha_q/G\alpha_{11}\) and PECAM-1 (data not shown), and we found G\(\alpha_q/G\alpha_{11}\) to be acting upstream of PECAM-1. We also demonstrate that the P2Y2–G\(\alpha_q/G\alpha_{11}\)-mediated pathway is responsible for flow-induced NO formation by eNOS and for maintaining basal blood pressure. Acute eNOS activation through P2Y2 and G\(\alpha_q/G\alpha_{11}\) may involve a transient increase in [Ca\(^{2+}\)] which leads to Ca\(^{2+}\)/calmodulin-dependent eNOS activation. However, sustained activation of NO formation in response to shear stress is likely to involve P2Y2 and G\(\alpha_q/G\alpha_{11}\)-mediated AKT activation, which leads to phosphorylation of eNOS at serine 1177 (7, 8). The fact that acute loss of endothelial P2Y2–G\(\alpha_q/G\alpha_{11}\)-mediated signaling strongly reduces eNOS activity in vivo, resulting in arterial hypertension, indicates that the P2Y2 and G\(\alpha_q/G\alpha_{11}\)-mediated signaling pathway in endothelial cells is constantly activated to sustain endothelial NO formation and to mediate fluid shear stress–induced vasodilation. The degree of arterial hypertension after long-term loss of endothelial G\(\alpha_q/G\alpha_{11}\) is much smaller than after acute induction of endothelial G\(\alpha_q/G\alpha_{11}\) deficiency (31), suggesting that local and systemic counterregulatory processes are induced by the acute reduction in flow-induced G\(\alpha_q/G\alpha_{11}\)-mediated vasorelaxation.

In recent years, several GPCRs have been shown to respond to different mechanical stimuli in vitro (40). Of those, the G\(\alpha_q/G\alpha_{11}\)-coupled bradykinin B2 receptor showed conformational changes in response to fluid shear stress, demonstrated by intramolecular Förster resonance energy transfer of the heterologously expressed receptor fused with 2 fluorescent proteins (41). However, it is not known whether this also occurs in the WT receptor and results in activation of downstream signaling. In our expression analysis,
we did not find the B2 receptor consistently expressed in fluid shear stress–sensitive endothelial cells. Also, the sphingosine 1 phosphate receptor 1 (S1P1), which is widely expressed in different endotelia, has been involved in fluid shear stress sensing in vitro and in vivo (42), but it is not known whether endothelial S1P1 regulates vascular tone and blood pressure. However, given that S1P1 is coupled to G-type G proteins (43) and thereby activates downstream signaling pathways other than P2Y2, it is likely that S1P1 mediates different flow-induced endothelial effects, such as endothelial cell alignment (42). It is also possible that both receptors to some degree synergize in endothelial flow sensing.

Although, the P2Y\textsubscript{2} and G\textsubscript{11}/G\textsubscript{i12}-mediated signaling pathway is upstream of the mechanotransducing pathways described thus far, the question remains of how P2Y\textsubscript{2} is activated in response to flow. Evidence has been provided that GPCRs such as the S1P1 and the bradykinin B2 receptors can be activated by flow in a ligand-independent manner (41, 42). On the other hand, it is well known that increased shear stress on endothelial cells induces the release of the P2Y\textsubscript{2} agonist ATP and that ATP can activate P2Y\textsubscript{2} in isolated endothelial cells (36–39). Consistent with this, we found that fluid shear stress induced the release of considerable amounts of ATP from endothelial cells, and the ATP-degrading enzyme apyrase has been shown to block flow-induced increases in intracellular $[\text{Ca}^{2+}]$ (44). In addition, we found that flow-induced AKT and eNOS phosphorylation, in addition to NO formation, was strongly reduced in the presence of apyrase, indicating that ATP mediates fluid shear stress–induced effects. Thus, flow-induced endothelial release of ATP through as-yet poorly understood mechanisms (45) is the most likely flow-dependent activation mechanism of P2Y\textsubscript{2}.

Also, ionotropic purinergic receptors have been involved in flow-dependent endothelial effects, and, in particular, P2X4 has been suggested to mediate ATP-induced Ca\textsuperscript{2+} influx in endothelial cells as well as flow-dependent control of vascular tone (34, 46). However, a more recent study indicated that ATP-induced Ca\textsuperscript{2+} mobilization and NO production in vitro involve P2X2, rather than P2X4 receptors (47), and it remains unclear whether the elevated blood pressure and defective adaptive vascular remodeling seen in a global, nonconditional knockout of the P2X4-encoding gene in mice can be attributed to the loss of P2X4 in endothelial cells or other cells (34).

The ability of the endothelium to sense fluid shear stress and to transmit this information into an intracellular signal is a fundamental function of the endothelial cell layer of blood vessels. Shear stress sensing and transduction control vascular tone and morphogenesis and affect susceptibility to diseases, such as atherosclerosis and hypertension. We have identified a critical mechanosensing pathway consisting of P2Y\textsubscript{2} and G\textsubscript{11}/G\textsubscript{i12} that is required for flow-dependent NO formation and regulation of vascular tone in vitro and in vivo. This pathway appears to be upstream of all mechanotransducing pathways described so far, and it may be interesting to investigate its function in other responses of endothelial cells to fluid shear stress as well as in vascular diseases such as hypertension.

Methods

Reagents. ACh, ATP, UTP, ATP\textsubscript{S}, thrombin, carbachol, ionomycin, phenylephrine, PP2, and tamoxifen were purchased from Sigma-Aldrich. Insulin was purchased from Gibco. SNP was obtained from Alexis Biochemicals. Apyrase was purchased from New England Biolabs Inc. (catalog M0393L). Ki8751 was obtained from Toocris. The P2Y\textsubscript{2} receptor antagonist AR-C118925 was synthesized in the laboratory of Christa E. Müller (University of Bonn, Bonn, Germany); the purity was approximately 95% (determined by HPLC-UV/MS and $^1$H- and $^{13}$C-NMR). U46619 was from Cayman Chemical. Antiphosphorylated eNOS (mouse Si176, human Si177, and bovine Si179; catalog 9571); antiphosphorylated ADT (S473; catalog 4060); anti-AKT (catalog 9272); anti-GAPDH (catalog 2118); and antiphosphorylated SRC kinase (Y416; catalog 2113) Abs were obtained from Cell Signaling Technology. Antiphosphorylated tyrosine Ab (4G10; catalog 05-1050X) was obtained from EMD Millipore. Anti-eNOS Ab was purchased from BD Biosciences (catalog 610296). Anti-G\textsubscript{11}, P2Y\textsubscript{2}, and P2X4 were from QIAGEN. The target sequences of siRNAs directed against RNAs encoding G\textsubscript{i11}, P2Y\textsubscript{2}, and P2X4 were as follows: G\textsubscript{11} (human) 5′-CAGGACACATCGTTCGATTTA-3′ and 5′-CAGGAGTCTGATGACAG-3′; G\textsubscript{11} (human) 5′-CTCAACAATGACGGACAACG-3′ and 5′-AACGTGACATCCATCATGTTT-3′; G\textsubscript{11} (bovine) 5′-CAGCAGCTGTTGATCAGAAA-3′ and 5′-AACAATTTGCAATAC-3′; G\textsubscript{11} (bovine) 5′-CCATGATGGTGCTCT-3′ and 5′-AACCAGGCCCGTGGTGTCCTGA-3′; and G\textsubscript{11} (bovine) 5′-CAGCACATCGTTCGATTTA-3′ and 5′-CAGGAGTCTGATGACAG-3′. For the determination of intracellular $[\text{Ca}^{2+}]$, cells were transfected with siRNAs using Opti-MEM and Lipofectamine RNAiMAX (Invitrogen) as described previously (48). SiRNAs used for the screen were pools of siRNAs of an siRNA library directed against 514 genes encoding GPCRs including 407 non-olfactory human GPCRs and 86 olfactory human GPCRs (QIAGEN) targeting the same RNA. siRNAs against G\textsubscript{i11}, P2Y\textsubscript{2}, and P2X4 were from QIAGEN. The targeted sequences of siRNAs directed against RNAs encoding G\textsubscript{i11}, P2Y\textsubscript{2}, and P2X4 were as follows: G\textsubscript{11} (human) 5′-CAGGACACATCGTTCGATTTA-3′ and 5′-CAGGAGTCTGATGACAG-3′; G\textsubscript{11} (human) 5′-CTCAACAATGACGGACAACG-3′ and 5′-AACGTGACATCCATCATGTTT-3′; G\textsubscript{11} (bovine) 5′-CAGCAGCTGTTGATCAGAAA-3′ and 5′-AACAATTTGCAATAC-3′; G\textsubscript{11} (bovine) 5′-CCATGATGGTGCTCT-3′ and 5′-AACCAGGCCCGTGGTGTCCTGA-3′; and G\textsubscript{11} (bovine) 5′-CAGGACACATCGTTCGATTTA-3′ and 5′-CAGGAGTCTGATGACAG-3′.

Shake stress assays, Western blotting, IP. For biochemical experiments, cells were exposed to flow using a parallel-plate flow chamber from ibidi (ibidi GmbH). For IP experiments after flow, the BioTech-Flow System (MOS Technologies) was used to expose cells to fluid shear stress. Cells were lysed in Triton X-100 buffer supplemented with protease and phosphatase inhibitors. Isolated mesenteric arteries were lysed by radioimmunoprecipitation assay (RIPA) buffer. Soluble supernatants were incubated with appropriate Abs and protein A/G PLUS-Agarose (Santa Cruz Biotechnology Inc.) overnight at 4°C. The beads were washed 5 times with lysis buffer. IPs or total cell lysates were subjected to SDS-PAGE and transferred to nitrocellulose membranes. Membranes were probed with primary and horseradish peroxidase–conjugated secondary Abs (Cell Signaling Technology) and were developed using the ECL detection system (Thermo Scientific Pierce, Life Technologies).

Determination of $[\text{Ca}^{2+}]$. For the determination of intracellular Ca\textsuperscript{2+} concentration, cells were placed in a microfluidic plate (Flux-
ion Biosciences) and loaded with Fluo-4 AM (Molecular Probes, Life Technologies). Laminar shear stress was generated using the BioFlux 200 System (Fluxion Biosciences), and live cell images were acquired with an Olympus IX81 microscope.

**Determination of ATP concentration.** Cells were kept under static conditions or exposed to fluid shear stress, and the ATP concentration in the supernatant was determined at the indicated time points (see Figure 4E) using a bioluminescence assay (catalog A22066; Molecular Probes, Life Technologies) according to the manufacturer’s instructions. Luminescence intensity was measured with a FlexStation 3 (Molecular Devices). ATP amounts were calculated with a calibration curve constructed using ATP standards. Parallel determination of lactate dehydrogenase (LDH) activity (catalog 10008882; Cayman Chemical) showed no LDH activity, excluding that cell damage contributed to the increased ATP release under fluid shear stress.

**Animal models.** All mice were backcrossed onto a C57BL/6N background at least 8 to 10 times, and experiments were performed with littermates as controls. Male and female animals (8–12 weeks old) were used unless stated otherwise. Mice were housed under a 12-hour light/12-hour dark cycle, with free access to food and water and under specific pathogen–free conditions unless stated otherwise.

The generation of inducible endothelium-specific Gαq/Gα11-deficient mice (Tie2-CreER; Gnaqfl/fl) was described previously (31). The generation of mice with inducible endothelium-specific deficiency of P2Y2 (Tie2-CreER; P2y2fl/fl) is described in Supplemental Figure 5. The Journal of Clinical Investigation

**Telemetric blood pressure measurements.** Measurements were performed in conscious, unrestrained mice with a radiotelemetry system (PA-C10; Data Sciences International) as described previously (49). Mice were caged with blinded identity and in random order.

**Determination of nitrate and nitrite levels.** Nitrate and nitrite (NOx) levels in plasma were measured with a highly sensitive HPLC system (ENO-20; Eicom) as described previously (50). Blood was collected from the retro-orbital sinus and immediately centrifuged at 6,800 g for 5 minutes at 4°C. Five days before the experiments commenced and throughout the observation period, animals were put on a standard chow diet (Lantmännen, Sweden) specifically selected for its low NOx content. Mice were caged with blinded identity and in random order. Flow-induced NOx release from endothelial cells in vitro was measured using a nitrate/nitrite fluorometric assay kit from Cayman Chemical according to the manufacturer’s instructions.

**Pressure myography.** Animals were sacrificed, and the mesenteric arterial bed was removed and placed in ice-cold Krebs buffer (118.1 mM NaCl, 4.8 mM KCl, 2.5 mM CaCl₂, 1.2 mM MgSO₄, 1.2 mM KH₂PO₄, 25 mM NaHCO₃, 9.3 mM glucose, and 0.026 mM EDTA, pH 7.4, supplemented with 1% BSA). Arteries of the third or fourth branch were removed from the mesentery by gently peeling away the adventitia and were mounted in the proper proximal–distal orientation between 2 glass micropipettes seated in a chamber (Danish Myo Technology A/S). The inflow cannula was fixed, while the outflow cannula allowed for length adjustment along the longitudinal axis. The artery was secured on both ends by a 10.0 nylon suture and perfused with low-flow (5 μl/min) to remove any blood from the vessel lumen. The external diameter of the artery was visualized and recorded with a CCD camera using MyoVIEW software (Danish Myo Technology A/S). The temperature of the chamber was kept at a constant 37°C. The mounted artery was initially pressurized to 20 mmHg under no-flow conditions and incubated for 30 to 40 minutes. Pressure was then increased to 70 mmHg and the vessel was incubated for 10 minutes to allow it to reach a steady-state diameter. Vessels were contracted with 50 to 150 nM U46619 to 40% to 50% of the passive diameter. After reaching a stable baseline, flow was increased in a stepwise manner by changing the pressure of the inflow and outflow sides inversely, thereby creating a pressure difference across the arteriole without altering the intraluminal pressure. The viability of the vessel was verified at the end of the experiment by dilating the vessel with ACh (10 μM) or SNP (100 μM). Arteries showing less than 60% relaxation were considered damaged and were omitted from further analysis. Vasodilation to flow was calculated as a percentage of the U46619-induced contraction as described previously (51) by the following equation: percentage of relaxation = 100 × (DPD – DU46619)/(DPD – DU46619), where D represents the external diameter of the vessels; Dp is the vessel diameter during flow; and DPD is the diameter after U46619 contraction.

**Expression analysis.** RNA isolation and transcription were performed as described previously (48). Primers were designed with the online tool provided by Roche, and quantification was performed using the LightCycler 480 Probe Master System (Roche). Genomic DNA was used as a universal standard to calculate the gene copy number per nanogram of RNA. Relative expression levels were obtained by normalization with GAPDH or 18S values.

**qPCR primer sequences.** The qPCR primer sequences were as follows: GNAQ (human) forward: 5′-GACTACTTCCCAAGAATGTGAGC-3′, reverse: 5′-GGTTCAAGCTCCAGAAACATC-3′; GNAI1 (human) forward: 5′-GATCCAGGAATGCTACGAC-3′, reverse: 5′-GGTCAACGTCCGTCAGATTGAG-3′; Gnaq (mouse) forward: 5′-GCATCTTCCCAAGAATGTGGAGC-3′, reverse: 5′-TCAGGATGAATTCCTGAGCTG-3′; Gna11 (mouse) forward: 5′-CAGTGGCATCATCGAGTACC-3′, reverse: 5′-GATCCACCTTCCTGGCCTCT-3′; Gnaq (bovine) forward: 5′-TGGTCCCGGTCTACCTCTGAG-3′, reverse: 5′-TAGGGGTATCTTGGCTGTC-3′; Gna11 (bovine) forward: 5′-GAGCGACCTTATCAACGAGA-3′, reverse: 5′-GATGTTCTGGTACACCAGTTTGG-3′; GAPDH (human) forward: 5′-GAT CCTGGGCTTACACTGTA-3′, reverse: 5′-CCAGGCTGCAAGTTTTGAG-3′; GAPDH (mouse) forward: 5′-AGCCTTGATCAGCTATAAGGAG-3′, reverse: 5′-TTTGAGTCTTTAAGGTGTCG-3′; GAPDH (bovine) forward: 5′-CTACCAGGCGGTCTTTTAAAT-3′, reverse: 5′-GAAGGTTCAATGAAAGGGGTC-3′; P2Y2 (human) forward: 5′-TAACTCGTGAGGACACCTC-3′, reverse: 5′-CTGAGGCTTGGCCACAGA-3′; P2Y2 (mouse) forward: 5′-GGTTACCTGGCGGTCTTTCA-3′, reverse: 5′-GGTGGATCAGGGCGCTGTA-3′; P2Y2 (bovine) forward: 5′-AGAATCTCAGGGGGGACAGA-3′, reverse: 5′-CAGCCAGATGTCATTAGTGTC-3′; P2X4 (human) forward: 5′-AGCCCAACGAAAGAGAAG-3′, reverse: 5′-TCTCTGTTGGATGTGTGTC-3′; 18S (mouse) forward: 5′-GCAATTATCCCCACTAGA-3′, reverse: 5′-GGAGGAAAGGAGATGCTCA-3′.

**Statistics.** Trial experiments or experiments performed previously were used to determine sample size with adequate statistical power. Samples were excluded in cases where RNA and cDNA quality or
tissue quality after processing was poor (below commonly accepted standards). Data are presented as the mean ± SEM. Comparisons between 2 groups were performed with an unpaired 2-tailed Student’s t test, and multiple group comparisons at different time points were performed by 2-way ANOVA, followed by Bonferroni’s post-hoc test. A P value of 0.05 or less was considered statistically significant.

Study approval. All procedures involving animal care and use in this study were approved by the local animal ethics committees (Regierungspräsidia Karlsruhe and Darmstadt, Germany).
