## Supplemental Data

## Methods

 flanking exons 1-2 (Srsff ${ }^{\text {fl }}$ ) and albumin-Cre (Alb-Cre) transgenic mice (B6.Cg-Tg(Albcre) $21 \mathrm{Mgn} / \mathrm{J}$ ) were obtained from The Jackson Laboratory (Bar Harbor, Me). The Srsf $2^{\text {fl }}$ allele was genotyped with forward primer $5^{\prime}$-GTTATTTGGCCAAGAATCACA- $3^{\prime}$ and reverse primer $5^{\prime}$-AACCTTGTTCGTTGACCGAT-3'; this reaction yields a 321-bp product for the wild-type allele and a 410-bp product for the $\operatorname{Srsf} 2^{\text {fl }}$ allele. Cre-mediated recombination excises exons 1-2 and inactivates $\operatorname{Srsf} 2$ (42). The $\operatorname{Srsf} 2$ knockout allele was detected by PCR with forward primer 5'-GTTATTTGGCCAAGAATCACA-3' and reverse primer 5'-ACTCTCCACACCTAGTATTGTAAA- $3^{\prime}$; this reaction yields a 518 -bp product. The Alb-Cre transgenic allele (Alb-Cre ${ }^{+}$) was genotyped with forward primer 5'-GCATTACCGGTCGATGCAACGAGTGATGAG-3' and reverse primer 5'-GAGTGAACGAACCTGGTCGAAATCAGTGCG-3', which yields a 408-bp product. The $L m n a^{\mathrm{G} 609 \mathrm{G}}$ allele was created with a sequence-replacement vector as described (21), except that a $\mathrm{C}>\mathrm{T}$ mutation in codon 609 was introduced into the $5^{\prime}$ arm of the Lmna targeting vector by sitedirected mutagenesis (QuikChange kit, Stratagene). After electroporating the vector into 129/OlaHsd embryonic stem (ES) cells, targeted ES cell clones were identified by long-range PCR (TaKaRa LA Taq polymerase, Clontech). Targeted ES cells were injected into C57BL/6 blastocysts, and the resulting chimeras were bred with C57BL/6 females to generate heterozygous knock-in mice, which were then intercrossed to generate homozygotes. All mice were fed a chow diet and housed in a virus-free barrier facility with a 12-h light/dark cycle.

Hepatocyte isolation. Srsf2 $2^{\mathrm{fl} / f 1}$ mice were bred with Alb-Cre ${ }^{+}$Srsf $^{\mathrm{fl} /+}$ mice to generate $\operatorname{Srsf} 2^{\mathrm{fl} / \mathrm{fl}}$ and $\operatorname{Srsf} 2^{\mathrm{fl} / \mathrm{fl}}$ Alb-Cre mice. At age P23, the mice were anesthetized and the inferior vena cava cannulated with a 22-gauge catheter. The portal vein was cut, and the liver was perfused with warm PBS, followed by liver digest medium (17703-034, Invitrogen) containing $0.015 \%$
collagenase IV (Gibco). The liver was removed, dispersed, and filtered through a $70-\mu \mathrm{m}$ basket. Cells were suspended in William's E medium (Gibco) and fractionated on a Percoll gradient (P1644, Sigma-Aldrich). Hepatocytes were isolated, and extracts were prepared for protein and RNA analyses.
$L M N A$ reporter construct. A $L M N A$ fragment spanning exons $8-12$ (including the $3^{\prime}$ UTR) was amplified from human genomic DNA with forward primer 5'-GAGATGATCCCTTGCTGACTTACC-3' and reverse primer 5'-CCAAAGTGCTCTGATCTCTAATTGT-3'. The fragment was purified and subcloned into pGEM-T (A3600, Promega; Madison, WI), and the sequence was verified by sequencing. Three potential SRSF2 sites (site-1, site-2, and site-3) in exon 11 were mutated individually (or in combination) by site-directed mutagenesis with the QuickChange kit (Agilent Technologies; Santa Clara, CA). SRSF2 site 1, located between nucleotides 24-31 of exon 11, was mutated with forward primer $5^{\prime}$-GTACTCAGCGGGTTCGCCCGAGCTGCTG-3' and reverse primer 5'-CAGCAGCTCGGGCGAACCCGCTGAGTAC-3'. SRSF2 site 2, located between bases 4653 of exon 11, was mutated with forward primer 5'-GCTGAGTACAACCTGAGATCTCGCACCGTGCTGTGC-3' and reverse primer 5'-GCACAGCACGGTGCGAGATCTCAGGTTGTACTCAGC-3'. SRSF2 site 3, located between bases 54-60, was mutated with forward primer 5'-CCGCACAGCACTGTGCGCGAGCG-3' and reverse primer $5^{\prime}$-CGCTCGCGCACAGTGCTGTGCGG-3'. The SRSF6 site, located between bases 64-69 of exon 11, was mutated with forward primer 5'-GGGACCCCGCCGAGTTCAACCTGCGCT-3' and reverse primer 5'-AGCGCAGGTTGAACTCGGCGGGTCCCC-3'. The cytosine in codon 608 (c. 1824 or base 126 of exon 11) was changed to a thymidine with forward primer 5'-AGCCCAGGTGGGTGGACCCATCTCC-3' and reverse primer 5'-GGAGATGGGTCCACCCACCTGGGCT-3'. All nucleotide changes were confirmed by DNA sequencing. A DNA fragment from exon 10 to exon 12 (including the $3^{\prime}$ UTR) was amplified
from each plasmid and subcloned into the $\beta$-globin reporter RHCglo (a gift from Dr. Thomas A. Cooper, Baylor College of Medicine; Houston, TX) with the In-Fusion HD kit (Clontech Laboratories; Mountain View, CA). Each fragment was amplified with exon 10 primer $5^{\prime}-$ ACCTCCAAGCTCCGGAGAAGTGGCCATGCGCAAGCTG-3' and exon 12 primer $5^{\prime}-$ ACCGCGGTGGCGGCCGCGCCAGGGGTAGAAACAACTAG-3' and subcloned with restriction enzymes BspEI and NotI. All constructs were verified by DNA sequencing.

Table 1. Sequence of ASOs and primers.

Supplemental Figure 1. Screening of Lmna antisense oligonucleotides that affect lamin C/prelamin A mRNA splicing. Wild-type mouse embryonic fibroblasts were transfected with ASOs corresponding to sequences in exon 10, intron 10, and exon 11 of Lmna. After 2 days, extracts were prepared and analyzed by western blotting with antibodies against lamins $\mathrm{A} / \mathrm{C}$ and actin (as a loading control). Cells treated with ASO E11-31 are marked with an asterisk.

Supplemental Figure 2. Modulation of LMNA alternative splicing with exon 11 ASOs. (A) Longer ASOs are more effective in promoting lamin C splicing. Wild-type cells were transfected with E11-31 ASOs of different lengths ( $16 \mathrm{nt}, 18 \mathrm{nt}, 20 \mathrm{nt}$ ). After 2 days, transcript levels were measured by qRT-PCR. (B) Multiple ASOs near E11-31 promote lamin C splicing. Human fibroblasts (AG2429) in duplicate were transfected with ASOs. After 3 days, lamin A and lamin C protein levels were measured by western blotting. The bar graph shows lamin protein expression relative to cells treated with a scrambled ASO (set at a value of 1.0). (C) RT-PCR showing that ASO E11-31 does not increase usage of the HGPS donor splice site. Triplicate wells of human fibroblasts (AG2522) were transfected with ASO E11-31 or a scrambled control ASO. After 2 days, prelamin A transcripts were amplified by RT-PCR. RNA from
nontransfected HGPS cells (AG11513) was included as a control (HGPS). Only trace amounts of progerin transcripts were detected in the ASO-treated cells. (D) Western blot analysis showing that the effects of ASO E11-31 on lamin A and progerin levels in HGPS cells are dose dependent. (E) ASO E11-31 reduces prelamin A and progerin transcript levels in multiple HGPS cell lines. Wild-type cells (AG2429 and AG2522) and HGPS cells (hTERT immortalized 75-8, AG11513, and AG1972) were transfected twice with ASO E11-31 or transfection reagent alone (NTC). One day after the last transfection, transcript levels were measured by qRT-PCR and expressed relative to the NTC (set at a value of 1.0). (F) Western blot analysis showing that ASO E11-31 reduces lamin A and progerin protein levels in multiple HGPS cell lines.

Supplemental Figure 3. Location of potential exonic splice enhancer (ESE) binding sites within exon 11 of $L M N A$. Exon $11 L M N A$ sequences were analyzed with the program ESE Finder. Six potential ESE binding sites were identified: 3 SRSF2 sites (red and purple), one SRp55 site (blue), and 2 SF2/ASF sites (green). The sequences of several ASOs used in this study are shown at the bottom of the schematic.

Supplemental Figure 4. ASO E11-31 treatment lowers progerin levels in the aortas of Lmna ${ }^{\text {G609G/G609G }}$ mice and improves the arterial disease phenotype. (A) Western blot showing ASO E11-31 lowers progerin levels in the aorta of Lmna ${ }^{\mathrm{G} 609 \mathrm{G} / \mathrm{G} 609 \mathrm{G}}$ mice. Lamin A, progerin, and lamin C levels in four untreated $L m n a^{\mathrm{G} 609 \mathrm{G} /+}$ mice (609/+) and three Lmna ${ }^{\mathrm{G} 609 \mathrm{G} / \mathrm{G} 609 \mathrm{G}}$ mice (609/609) treated with ASO E11-31 (ASO) or a scrambled ASO (Con) are shown. Actin levels were measured as a loading control. The results are shown for two Lmna ${ }^{\mathrm{G} 609 \mathrm{G} / \mathrm{G} 609 \mathrm{G}}$ mice treated with ASO E11-31 (E11-31 ASO2 \& E11-31 ASO3), and a Lmna $a^{\mathrm{G} 609 \mathrm{G} / \mathrm{G} 609 \mathrm{G}}$ mouse treated with the control ASO (Con ASO3; not reported in Figures 6C-6D). (B) ASO E11-31 lowers progerin levels in the aorta. Progerin levels shown in panel A were measured by laser scanning and normalized to actin levels. Levels reported for the Lmna ${ }^{\mathrm{G} 609 \mathrm{G} /+}$ mice are the average of four animals. (C) Histological images showing less disease in the aortas from Lmna ${ }^{\mathrm{G} 609 \mathrm{G} / \mathrm{G} 609 \mathrm{G}}$ mice treated with ASO E11-31. Images (10x magnification) of Masson's trichrome-stained cross sections through the ascending aorta are shown for one wild-type, two Lmna ${ }^{\mathrm{G} 609 \mathrm{G} / \mathrm{G} 609 \mathrm{G}}$ mice treated with a control ASO (Con ASO2 and Con ASO3), and two Lmna ${ }^{\mathrm{G} 609 \mathrm{G} / \mathrm{G} 609 \mathrm{G}}$ mice treated with ASO E11-31 (E11-31 ASO1 and E11-31 ASO3). White colored bars identify the adventitia. Scale bars, $100 \mu \mathrm{~m}$.
